

The Booming Bulls Method

A study guide derived from the complete channel archive of Anish Singh Thakur's trading education videos

About this book. This is an independent study guide to the publicly available video work of Booming Bulls Academy (Anish Singh Thakur) (<https://www.youtube.com/@BoomingBulls>). It was compiled by reading the transcripts of 2315 videos published between 2020-05-17 and 2026-08-17, extracting the ideas taught in them, and reorganising that material by concept rather than by upload date. It is not affiliated with, authorised by, or endorsed by Booming Bulls Academy (Anish Singh Thakur).

Everything presented as Booming Bulls Academy (Anish Singh Thakur)'s view is paraphrased from what was actually said on the channel. Every such claim was checked against a source record before this book was assembled, and the complete list — every claim, matched to the exact video and the exact second it was said — is in the Source Index at the back, so any passage in this book can be checked against the original in a few seconds. The inline markers used to cross-check that during compilation are omitted here for readability; nothing in this book is

uncited, it just isn't interrupted by its own footnotes. If you find this material useful, the original videos are the primary source and are worth watching in full.

Passages set in marked **Editor's note** boxes are explanatory context added by the compiler — definitions, background mechanics, worked examples — to make the material easier to follow. Those boxes are never Booming Bulls Academy (Anish Singh Thakur)'s claims. Where the channel does not cover something, this book says so rather than filling the gap.

Educational content, not financial advice. This book describes trading and investing methods that use leveraged instruments (options, futures, forex, and leveraged crypto positions), which can produce losses larger than the capital deployed. Nothing in this book is a recommendation to buy, sell, or hold any security or instrument, and past results described by the creator are his own reported claims, not verified performance and not a guarantee of future results. If you are affected by financial loss or trading-related distress, see the note in the Psychology chapter and Appendix F for support resources — this book and the channel it studies are not a substitute for professional financial, legal, or mental-health advice.

Chapter 1 — Who He Is and What He Teaches

In this chapter: the account Anish Singh Thakur gives of his own background, the claims he makes about his results, his stated practice of publishing losses alongside wins, and the shape of what the channel teaches — the syllabus, the timeline he puts on it, and who he says it is and is not for.

Everything marked as his is drawn from the videos and cited to the clip. Where this book explains something he doesn't, the passage is set off as an Editor's note. That boundary is why this chapter can report his claims about his own trading at all: they appear as *claims he makes on camera*, cited so a reader can go and listen, never as verified fact.

1.1 The story he tells about himself

He dates his entry to 2018 and says that for the first two years he followed no risk management at all — pure gambling. His origin is a loss story: he started by losing heavily in options, having made money first and then put all of it back in.

The dates he gives for his own experience don't agree, and this book doesn't reconcile them: over four years in December 2021, six years of

active participation in August 2024, fifteen years in May 2024. Treat 2018, which he gives most often and most precisely, as load-bearing. Before trading there was a company, Technobase, started at twenty-one or twenty-two, which shut down with the biggest loss in it his own. He's an engineering dropout and says he never promoted dropping out as a path.

His learning ran through paid education and two scams: a tip provider who refused to teach him and refunded him, which convinced him the tips weren't backed by any teachable method, and sixty to seventy thousand rupees to an educator selling tiered memberships off profit screenshots who never taught. He then learned from YouTube and Mumbai seminars, and paid roughly eighty thousand rupees for a course with three days of live trading. He totals his education spending at about one lakh rupees; the courses, he says, moved him neither ahead nor behind but saved him time, and his real education came from his own failures and losses.

1.2 Dubai, the team, and the end of the paid course

The 2020 lockdown is the low point in his telling — finances, relationships and trading all going badly, the setup he gives for starting to meditate. He dates his start in forex to 2020 and says the biggest reason he later shifted to Dubai was to trade forex properly with large capital — framed as early as January 2021 as his personal solution to margin and legality problems rather than a recommendation.

He says he used to teach five hundred to eight hundred people at a time and stopped because he ran out of time and wanted to focus on trading, dating the stop to mid-2024, after opening a trading floor and building a team of thirty to thirty-five. As of 2026 he states he has no paid course and not a single paid service, that his company is SEBI registered in India, and that the registered service they used to run has been made free.

Editor's note — what "SEBI registered" does and does not mean

here He asserts the registration and mentions one consequence: clauses in it mean they cannot trade in their own name. He never states the category. SEBI licenses several distinct things — research analysts, investment advisers, portfolio managers, brokers — and a registration permitting published research is not one permitting advice to individuals on their money. This book takes no position on his status; it reports only that he asserts it.

1.3 What he claims about his own results

These are claims made on camera, usually while screen-sharing an account. Nothing here has been verified.

In April 2022 he said his trading capital was above one crore rupees, offered to establish that his caution wasn't a small-account constraint; in June 2025, that he takes nobody's money because the five to seven crore

he has is enough. In December 2024 he showed two accounts, roughly sixty-nine thousand dollars of profit on one and about forty-three thousand three hundred on the second, each from a ten thousand dollar deposit, explicitly deducting the deposits. On win rate, in October 2024 he said he was earning at fifty to fifty-five percent and expected sixty-eight to seventy-two over following years — a forward expectation, not a record.

The losses are stated as plainly. In November 2025 he opened a video saying he'd booked a three-crore loss the previous day and took full responsibility — two crore of his own capital plus one crore of recent profit given back — with the lesson that being technically skilled doesn't protect you if your rules aren't clear. In April 2026 he said that since making his P&L public that month he'd lost every day, and asked whether that made him a bad trader.

Editor's note — why self-reported results are weak evidence He offers screen-shared accounts and a public verification link as proof, using the read-only investor password rather than the trading password, exposing only balance, account number and name. That's a real step above a screenshot, but not an audit: a connected account cannot show accounts closed, never connected, or capital held elsewhere, and a track record can be started, abandoned and restarted at will. He never claims an audited result.

1.4 Publishing the losses, and disclosing the incentives

What's distinctive here is not that he shows profits but that he builds videos around losses and says so as the explicit purpose. Anyone who only ever shows profits is fake, because trading is a mix of profits and losses. He walks failed trades on camera because he wants to be real and isn't showing magic. The practice recurs: filming on a day with five losing trades visible, as evidence he isn't cherry-picking; asking viewers to share the losing video too, since people only circulate the profit ones. His demonstration standard follows: not hand-picked dates but one random month scrolled through whole, taking targets and stops both without changing the rule mid-walkthrough. One tension he leaves unresolved: in the same 2024 video where he screen-shares live profit as proof an advice-giver actually trades, he says he stopped making big-profit videos because they were causing viewers more loss.

He extends the argument to how creators are paid. Any creator handing you a broker or funding-firm link earns commission on it, so a "not a sponsored video" disclaimer should be read as false — and he applies this to himself. He discloses receiving roughly thirty to thirty-five percent of the spread on trades placed by referred clients, win or lose, and says he refused an offer of forty to fifty percent of referred clients' *losses*. He will only recommend something he personally uses. He also admits his content is shaped by incentives: a thumbnail figure was there so people would click, and viewers should look at the management instead; he waited until a loss was recovered before making the video, because nobody watches

otherwise. Two self-corrections bear on how this book should be read: a strategy he published may have been tested only three months, against the three to four years he demands of viewers, and he no longer follows it, framing a published strategy as a snapshot rather than his current system.

1.5 What he teaches: the four quadrants and the order

Underneath several hundred videos is a stable curriculum: four quadrants a trader must give equal importance to before earning anything — technical, risk management, psychology and life management — with technical first, because for someone who doesn't know technical, no amount of risk management will matter. He repeated the frame years later as applying to every type of trading, with chart reading as quadrant one, and says that until you combine all four you cannot make money.

Within the technical quadrant the order is fixed: candlesticks, chart patterns, horizontal levels, supply and demand zones, small indicators, strategy, risk management, psychology, trading plan, life management, continuity; a 2026 restatement gives seven steps. What doesn't change is that chart reading comes before derivatives, and psychology and risk management are separate subjects rather than asides.

Two structural preferences run through it. Less material, not more: a limited number of setups rather than twenty-five; one strategy, one timeframe, one stock at the start; of roughly a hundred topics he's cut

about seventy and will teach the thirty that matter. And an order across markets: equity first, then options, then international markets and crypto — the order he learned them in.

One ordering question he answers inconsistently. In 2022 the psychological work came first — fix your belief before running behind strategies, options and futures. In 2025 and 2026 he says the opposite: most traders have no technical strategy at all, and psychology only matters for those who already have one. Read it as dated evolution; the later position is the one he currently holds.

1.6 How he says to study it, and how long it takes

The material must be practised, not watched. Watch with a notebook and pen; re-watch data-heavy lessons three or four times; write a three-or-four-line summary of any lesson in your own words, which he says matters more than everything the teacher said. He sets homework: run the next two months of a walkthrough yourself and comment how many targets and stops you got. And validation sits with the viewer: never believe anything you learn blindly, including from him — check it by backtesting.

The timelines don't all agree, partly because he measures different things. For knowledge alone: three to four months if diligent, scoped explicitly to the knowledge stage rather than the ability to apply it. For consistent profitability: roughly two years in 2020, sustained through one or two

hours of daily study rather than eight-to-fourteen-hour days; in 2025, at least one to two years working alone, or six to eight months with a team, mentors and resources, hedged immediately, alongside the statement that getting rich in a week is impossible. Options trading can only be done by someone three to four years in, and it took him about four to four and a half years to acquire the skills of holding winners, stopping at the stop and sizing positions.

The hedges shouldn't be dropped. You cannot make lakhs or crores after watching one video; even after a paid programme you won't be able to earn, because what you have is theory and not practice. He refuses to attach a monthly income figure to any of it, saying it's one thing to say you'll follow the system and another to actually follow it.

1.7 Who the material is for — and the job you do not quit

The audience is retail, mostly Indian, mostly people with a job, business or education already under way, and his advice on going full-time is the most consistent position in this material. Don't drop out of college to trade; absolutely don't quit a job; learn it alongside the job or education; take a part-time job rather than quitting a full-time one, because those who leave to trade full time lose more. He calls the thought of immediately dropping out the biggest trap, driven by reels from influencers earning through views rather than traders.

The route he does describe is gated, in a sequence not to be reordered: skill first, then saving, then considering quitting. The savings gate is roughly eighteen lakh of living-expense backup — two years at fifty thousand rupees a month, scaling with the family's expense — and it cannot double as trading capital, which he puts at a separate five to ten lakh. The performance gate is six months of consistent profit in the P&L record, converted to a percentage because the rupee amount on small capital is meaningless, and you may quit only once those percentage gains compare to your salary. A later formulation is two quarters consistently green while trading part-time.

He will also tell part of his audience the material is not for them: a settled businessman already earning and under stress from his work should not trade at all and should invest instead, and he tells the ordinary jobholder, developer or shopkeeper the same. That sits against his advice, in the same April 2024 video, that a beginner with no income who wants to create one should learn trading rather than invest. The distinguishing variable seems to be existing income and work stress, but he never states it as a rule.

Capital advice is protective in the same way. Beginners start with about two to five thousand rupees; a beginner with a full-time job caps what goes into learning at one lakh, in two tranches of fifty thousand. Keep capital very low at the beginning precisely because you will face losses while learning; expect not returns but survival, break-even and small profits. On outside money he warned never to take it until you have a firm grip on trading, a position he has partly reversed — around fifty thousand from a relative or close friend once your ROI is positive, naming it

himself as the thing he had earlier forbidden. The gate on positive ROI is the load-bearing part.

1.8 Courses, mentors, and not copying anyone

For someone who ran a paid academy, his position on paid education is markedly cool. Try the free route and read books first, and move to a paid programme only when you feel the need — he says explicitly he isn't telling you to buy his. A course is neither necessary nor sufficient; teenagers should focus on studies and learn free from YouTube until eighteen; nobody should spend money on courses they cannot afford. His ranking of routes puts reviewing your own mistakes first, then courses because they're designed as a sequence, then books, then YouTube. Nor is solitary self-teaching ideal: YouTube is good and the right mentor excellent, because a mentor shortens the learning period — a claim about speed, not exclusivity. Learn each topic from many sources, but following too many at once guarantees nothing happens; pick one method rather than argue the others are wrong.

The mentor question has a consistent boundary: learn from anyone, decide for yourself. Be independent, not dependent on any trainer, YouTuber or Telegram provider, and build your own strategies — said about himself as much as anyone, immediately after showing his own losing run. No one person, himself included, will change your life; enter and exit on your own rather than wait on what he did; you cannot copy someone's trading

style totally. After adopting another well-known trader's directional view and losing, his lesson was not to invest your money on anyone's words, because anyone can be wrong at any time. His own role is analysis and levels, not calls and tips, and he will not manufacture levels just to have levels to give, because viewers would trade them and take the loss. After all the years, he says he is still learning.

What he doesn't say about this

- **He never gives a full, dated account of his own trading record.** The figures are

episodic, and the verification link is a live feed from one or two connected accounts, not a record of everything he's traded. Nor does he reconcile the different dates he gives for his own experience: four years in 2021, six in 2024, fifteen in another 2024 video.

- **He does not explain what his SEBI registration covers.** He asserts it and

mentions one restriction on trading in the company's own name, but never the category or its scope.

- **He does not give a base rate for his own students.** He describes individuals who

succeeded, but never a figure for how many of the five hundred to eight hundred he taught at a time became profitable. His only success-ratio claim is an unsourced reading of a poll — five of ten fail, five pass.

- **He does not address the tax, legal or employer consequences of workarounds he

mentions in passing** — telling a viewer with a government job they can trade using an account in a sibling's, friend's or parent's name, with no caveat. This book flags that as an unqualified statement, not an endorsement.

Chapter summary

- He dates his own start to 2018 and says his first two years used no risk management

at all, describing his beginning as a heavy loss in options rather than a success.

- He says he spent roughly one lakh rupees on courses and seminars, was scammed twice,

and concluded that his real education came from his own losses.

- His claims about his own results are self-reported and episodic, and he offers a

public read-only account link rather than an audit as verification.

- He builds videos around his own losses as a stated policy, and discloses that

broker-link commissions exist including on his own channel.

- He has corrected himself in public on material points: that a strategy he published

was tested for three months rather than years, and that he no longer trades it.

- The curriculum is four quadrants — technical, risk management, psychology, life

management — taught in a fixed order with chart reading first and derivatives deferred.

- He puts three to four months on the concepts and one to two years on becoming a

trader working alone, and refuses to attach any income figure to either.

- He tells viewers not to quit a job or leave education to trade, and gates the

full-time move behind savings, a six-month or two-quarter record, and percentage gains that compare to a salary.

- He tells readers not to believe anything he teaches without backtesting it

themselves, and not to depend on any trainer, himself included, for decisions.

Try this

1. **Watch one lesson the way he asks it to be watched.** Pick a single teaching video, not a trade recap, and write notes with a notebook and pen as you go. Then close the video and write your own three-or-four-line summary — he says those lines matter more than everything the teacher said. 2. **Refuse to believe it yet.** Take the one testable claim in the lesson and check it on charts yourself. 3. **Do a month, not a highlight.** Take one random month on one instrument and step through the whole of it, counting how many targets and how many stop losses the rule produced. Write down the count, not the profit.

If step 3 produces a losing month, that's the result. He says he shows those too.

Chapter 2 — His Model of the Market

In this chapter: the three states he says price can be in, what he believes moves it, his account of why most retail traders lose, and the way market condition decides which setup he will even look at. It closes on his claim that the smart-money vocabulary is old price action under new names — the bridge into [[Ch. 4]].

2.1 Three states and no fourth

Everything rests on a claim from his earliest videos: the market moves in exactly three ways — up, down, sideways. Six years later the same split is still step two of his chart-reading process. Before you ask what to trade, you ask which state you're in.

Within a trend the path zig-zags rather than falling continuously, which is why levels are worth drawing at all; the typical sequence is breakout, pullback, continuation. No market moves in one direction indefinitely, so a pullback against your open profit is normal rather than alarming.

The second premise is that the next move is unknowable. Nobody, however experienced, can say in advance whether gold, silver or Bitcoin will rise or crash; stay away from market astrologers, and prepare rather

than speculate. A few recognisable states plus no ability to predict which comes next is the whole architecture — conditional plans rather than calls.

2.2 What he thinks moves price

Asked what affects a share's price, his answer is short: demand and supply, and news. The first half he teaches through an order book — price rises because of the buyer and falls because of the seller.

The news half is where the model becomes distinctive, because he doesn't believe news moves price when it arrives. Dow theory reduces to one usable point — every piece of information already in or coming to the market is discounted — which he reads as the market knowing in advance and always moving in anticipation, with no mechanism offered for how it knows. So the big move arrives before a result is published, not after — the retail mistake is expecting a good result to lift a stock that's already risen because the market knew. He states flatly that a stock does not rise on result day, having made its high before it.

Editor's note — where "the market discounts everything" breaks

His rule is a weak form of the efficient market hypothesis: prices embed public expectations, so only the *surprise* component should move them — which explains "buy the rumour, sell the news" without the market knowing anything in advance. The literature also documents post-earnings announcement drift, in which prices keep moving in the direction of a surprise for weeks afterwards. His flat claim that a stock does not rise on result day is stronger than the evidence supports.

2.3 Who is on the other side

He divides the market into three groups for six years running: institutions (FIIs and DIIs), high-net-worth or proprietary traders, and retail — people like us trading nominal amounts. The asymmetry is resources rather than intelligence, which he uses as a reason to upgrade your own setup rather than a claim that retail can't win: an institution is a whole building with departments for research, technicals, risk and news, while the retailer's analysis is a Telegram tip or a YouTube channel.

From roughly 2025 this hardens into a liquidity model. The market goes sideways when the big players are absent, then breaks the top of the range to hit stops once they want their fill; those sellers are selling in helplessness, stopped out rather than choosing. His leverage warning runs on the same mechanism: the market first takes out the weak hands and

only then starts the real rally. He puts himself and the viewer among the weak players, which is why he enters *with* the sweep rather than being swept.

Hence the corollary that anything obvious is dangerous because it's obvious. He books before an obvious moving-average target because lakhs of others will sell there, and avoids the 200-period moving average purely because everybody knows it. In 2024 he put a number on it: the obvious textbook signal works two or three times out of ten — an impression rather than a measurement — because everyone else sees the same chart.

2.4 How many lose, and why

His own numbers disagree: 90 to 95% facing losses, 93 with the surviving 7 being option sellers, 98 failing through bad disaster management. None carry a source. Against them stands a video attacking the statistic: from his own daily polls, after removing no-trade votes, 44% of voters lose and 56% are in profit, which he rounds to 50:50. The reframing is definitional — 99% holds only if "trader" means anyone who can operate a demat account and press buttons on tips — and his motive is that the belief is disabling: someone who believes they can't earn will lose even with ten crore and full training. The positions are never reconciled; the numbers are rhetorical. The causes are where the material becomes usable.

Failure begins before the first trade, with people trading without studying — like sitting an exam without preparation — most entering through Telegram tip channels or calls from Instagram and YouTube. His name for the method is *tukka*, guesswork, and he includes his own early career. The boundary is sharp: if you don't know your percentage returns, your edge or your win rate, you're gambling — and most know none of the three.

The second cluster is structural risk. No-stop-loss trading is the first reason accounts are lost, and he attributes the 90% who lose to using neither stop loss, nor risk management, nor position sizing. Leverage is the instrument of ruin — crypto losses almost always came from 25x, 50x or 100x. For his Indian audience the named enemy is option buying, the biggest enemy of retail traders for roughly 80% of his audience: it's impossible to make money buying a call or put every day, given theta decay and the market's tendency to range.

The third cluster is behavioural. Money goes, the trader works to recover exactly that money, and keeps losing; capital doubles, doubles again, then one loss takes it all. Traders lose their winners and hold their losers; they can't cut a loss because cutting it feels like ending the game; they raise risk after a loss. Overtrading is the single biggest killer, reframed in 2026 as psychological rather than a knowledge problem — traders know it's wrong while doing it.

Two hedges of his own must survive. He doesn't claim losses are avoidable: no amount of experience, technical knowledge or improved psychology lets a trader cut losses out. And he declines to blame those

who fail — trading is genuinely hard, and his harshness is about quitting rather than losing.

Editor's note — what the published data says His figures range from 44 to 99% with no sources. India's regulator, SEBI, studied individual traders in equity derivatives in January 2023 and found roughly nine in ten made net losses, the average loser losing far more than the average winner gained; a 2024 follow-up was similar. Two qualifications: the scope is equity F&O over a sample period, not a trading lifetime, and his own poll is self-selected from an education channel's followers. Neither supports a precise figure; both fit his qualitative point.

2.5 Psychology or strategy? A position that moved

The early position is psychology-first. In 2021 the market is identical for everyone — the difference is the psychology you impose on yourself; in a March 2022 class the losses come from poor self-control rather than technical failures; he has put the split at 80% psychology, 20% analysis.

The turn begins in September 2023, attributed to fieldwork: after meeting students at city meet-ups he concluded that what looks like a psychology problem — entering early, panicking — is usually an unclear technical setup. By May 2024, of traders claiming a psychology problem, about

70% instead have a technical problem they won't accept; by 2025, if you're losing and blaming psychology your strategy is not good. The tension is real: on 8 June 2025 he calls the psychology explanation false, eight days after a video whose four named reasons traders fail are all psychological, and never acknowledges it. This book reads the later position as being about *sequencing* rather than dismissal — he says in a 2026 video that he's arguing about order, not denying psychology matters — while noting he's said both, just as forcefully.

2.6 Condition first, setup second

The operational payoff is ordering: read the condition, then pick the instrument and setup to match. Trend is the number one consideration, and if a trade isn't with the trend you wait; however good the setup, if the trend is down then buying only produces a loss. Step one is moving to a higher timeframe, because that gives the trend, your location and the market's mood.

Condition also decides where he trades at all. Trade crypto in a bull phase and otherwise move away, because a bear-phase crypto market is mostly sideways or crashing with momentum even a trader can't manage. Money is money whichever market it comes from, so don't be attached to one instrument. On strategy: money as an option buyer is made only on trending days, while option selling applies at any time because it works in volatile or sideways markets.

From 2025 the check acquires a measurement: how much of the day's range is used. ATR is average true range, how much an instrument moves in a day, and step one is checking how much is consumed, because the space left decides whether a trade is on at all. Range mostly unconsumed, he takes breakouts and breakout-retests; mostly gone, he looks for reversals.

2.7 Bias: from "stay neutral" to "decide before you open the chart"

In August 2022 he told intraday traders to be totally neutral biased: the greater trend doesn't matter, focus on recent price action. By 2025-2026 it's reversed. Daily bias means deciding in advance whether you go buy-side or sell-side, and it's step three of his process, fixed before entering rather than during; his reason is that the market has become far more volatile with more participants. He concedes the opposite view is fair but asks how much success it produces.

The bias isn't an independent opinion — he derives it by combining the first two steps, higher-timeframe location and the range check, and once fixed it constrains what he looks for. The mapping inverts by day type. On a reversal day, position in the range sets it: top bearish, bottom bullish. On a breakout day with range unconsumed, the same locations give the opposite — lower end bullish, a break downward from the top bearish.

2.8 Sideways markets

Consolidation is the market having gone sideways for a while — his image is a person stepping back before jumping. The instruction for a range, unchanged since his first video, is symmetrical: buy at the bottom, sell at the top. In 2026 he still taught it as "ping-pong," with quality conditions — decent size and at least three or four touches on each side before the box is real.

The stronger claim is that consolidation is a *precursor*: it's the most important thing he needs before a trade, a breakout out of consolidation tends to be a good breakout, and a stock that keeps extending its consolidation is setting up a big move.

Against that sits the warning: it's really difficult to make money in a narrow sideways range; inside a zone you do nothing until price is out. In 2026 he said a sideways day is a bad day not to be traded, then allowed an exception for a range with a low-volume node in the middle. These are conditional, not contradictory — trading a sideways market is risky, but if it offers him an opportunity he should still take it — and what separates the cases is whether the range is structured enough, and whether he's being paid to sit still. The option seller earns if the market goes sideways, earns if it moves slowly, and loses less even when it goes against him; the buyer bleeds to theta decay and is finished if the index makes even one zigzag.

2.9 Volatility, events, and the clock

Volatility is the opposite of stability — price going very high or very low rather than staying steady — and he treats it as what decides how hard a market is to hold rather than as a signal. It's a property of the instrument first: gold is "the Bank Nifty of forex," fast enough to blow an account if the lot size is increased; a 2% move against 50x leverage blows the whole account, while 2% is nothing in crypto.

His rules adjust rather than override. Respect volatility and don't trail like a miser; never place a tight stop just above the swing where everyone expects it, because volatility will take it out. He also cuts size, reducing forex risk per trade during a volatile stretch — though he's also said volatility is not his problem, because the strategy guides him and there's a stop loss. The two reconcile only if the first is position sizing and the second psychology.

Events are their own category: when they arrive, many people get stopped out and the market prints a huge candle; the exact event should never be traded because the market chops rather than running one way. He reduces size on them. Budget days are also how he teaches IV crush across vocabularies — vega in the Greeks, implied volatility on the option chain, India VIX in plain words: whenever India VIX falls, the premium falls.

2.10 Gaps

A gap exists because the market never opens where it closed, the Indian market being shut while world markets keep running. Structurally a gap is information — there's always some reason behind it, so a large gap is evidence of strength in the direction it opened. Anticipating it is routine: he checks Singapore Nifty for where and how Nifty will open, and does nothing while pre-open data is still moving because the entire plan changes if the gap flips.

There are two tradeable structures and no more: a breakaway gap trade or a gap-fill trade, and if neither is available there's nothing to do. His most-used trigger is the break of the opening candle's low after a gap up, targeting the gap fill, with a win rate he puts at roughly six to seven out of ten — his impression rather than a measured statistic.

A gap against you is a plan-killer. A large gap up eats the move — with an 88-90 point gap on Nifty there's not enough range left for a worthwhile intraday option-buying trade. Hence a standing argument for forex — it runs continuously, so a stop loss being skipped doesn't arise — with Friday the exception, when forex does stop.

On holding overnight, nobody knows whether tomorrow gaps up or down, so carrying an open profit is putting the money on luck. It's not absolute — he's carried at-the-money puts overnight to capture an expected gap-down open with only a small part of his money in that leg. Gap exposure is a position-sizing decision, not a directional one.

Editor's note — why weekend gaps are the dangerous ones The exchange reopens through an auction rather than a continuous book, so there's no path of intermediate prices at which a resting stop could execute — a stop order is not a guarantee of loss size. The severity is unbounded: when the Swiss National Bank abandoned its euro floor in January 2015, EUR/CHF fell roughly 30% in minutes and several retail brokers ended the day with clients in debit balances — in the 24-hour forex market he describes as gap-free.

2.11 "The same concepts, new names"

The last piece of his market model is an opinion about vocabulary, and the bridge into [[Ch. 4]]. SMC — the smart-money-concepts label — renamed existing price-action ideas and made the English harder. Asked to judge SMC against other methods he refuses, comparing it to arguing over whether the left eye or the right eye is better. Stop arguing about method names and use whatever is working.

Alongside sits a claim pulling the other way: the market has changed since 2018-2021 and now traps far more, because everybody knows the classical concepts. In one July 2025 video he goes furthest, agreeing that support and resistance don't work in today's market and that trap and liquidity trading are what work now — against advice he gives earlier in the same video, unacknowledged. This book does not resolve it in his

favour: the weight of six years of teaching is that levels remain the substrate and traps are what happens *at* them.

What he doesn't say about this

- **He never sources a loss statistic.** Every failure-rate figure — 90 to 99% — is

asserted without citation, and his own subscriber poll gives a wildly different answer he never explains.

- **He never explains the discounting mechanism** — the market knows in advance and

moves in anticipation, with no account of how the information gets into price.

- **He gives no test for which state you're in.** Apart from the ATR-consumption check

there's no stated procedure for deciding when a trend has become a range or vice versa.

- **The psychology-versus-strategy question is left open**, argued both ways within a

fortnight in mid-2025 — as is the claim that support and resistance no longer work.

Chapter summary

- The market has three states — uptrend, downtrend, sideways — and identifying which one

you're in precedes every other decision.

- Nobody can predict the next move, including him; the answer is a conditional plan

rather than a forecast.

- Price moves on demand and supply, and on news already discounted before it's

announced — so the tradeable move happens *before* the event.

- Retail loses through guesswork, no stop loss, excessive leverage and option buying,

and the post-loss recovery loop — not because the market is unbeatable.

- His diagnosis moved from psychology-first (2021-2022) to strategy-first (2023-2026),

and he never reconciles the two.

- Condition decides instrument and strategy: option buying needs a trending day, option

selling survives a sideways one, and consumed range decides breakouts versus reversals.

- Consolidation is a build-up, not a dead zone — he wants it before a trade and trades

the side it breaks — while warning a narrow, unclear range is a day to sit out.

- Gaps carry information but destroy plans; on a gap day only two trades are available —

the breakaway gap and the gap fill — and otherwise nothing.

- He holds that the smart-money vocabulary is old price action relabelled, and that the

argument over method names is worthless.

Try this

Measure the range before you look for a trade. Add the ATR indicator on the one-hour timeframe, changed from its default 14 candles to 24 so it spans a day, and compute the previous day's range: draw a box from the prior day's high to its low, mark 50% of it, drop a line there, delete the box — the resulting number is the range you work with. At the start of your session, compare how far the instrument has already travelled today against that figure. If the move has already exceeded it, treat the intraday

range as consumed and plan a reversal; if not, look for breakouts. Do this for twenty consecutive sessions on one instrument, writing down the verdict before the session and what actually happened after it.

Chapter 3 — Vocabulary

In this chapter: the small set of words the rest of the book depends on — level, support, resistance, zone, area of interest, swing, trend, pullback, consolidation, trendline — defined the way he defines them. How he reads levels and trend across timeframes is Chapter 6; this is the glossary you need first.

3.1 A deliberately small vocabulary

Only two of TradingView's drawing tools matter for beginners — the trend line and the horizontal line — and the choice is geometric: the trend line for an angled level, the horizontal line for a flat one. Fibonacci and the pitchfork come later, so the two-tool rule is a starting point, not a limit. Chart reading needs only two concepts — market structure and liquidity — and no indicators. The shortness is deliberate — of "a hundred ways" to find an area of interest he picks three — and justified structurally: the market has only a limited set of structures, zig-zag, impulse-then-pullback, breakout-sideways-breakout. Technical analysis is defined operationally: where to buy, where to sell, where to book the target, where to cut the loss.

3.2 Level, support, resistance

Support is a price level that repeatedly stops the market from falling further; resistance is the mirror, a level the market is repeatedly unable to rise above — the chair holding him up at 100 rupees, and the ceiling price fails to cross. Draw a line where the bouncing happened.

"Repeatedly" is load-bearing, and the count is where he is genuinely imprecise: a minimum of two visible bounces, though two touches is only a *possible* area of interest; elsewhere a floor of three, four preferred; live, he counts in the three-to-six range. Read as a range: two makes a line worth drawing, three or more makes it worth trading.

The characteristic claim is that **support and resistance are not properties of the level**. A zone approached from below is resistance, the same zone from above is support, restated in the same words in 2021, 2022 and 2024; by 2026, no level is *born* as either — the name depends on where price sits, your ceiling fan being the neighbour's floor. Hence the **retest**: broken resistance acts as support on the return, and the reverse for broken support.

Two cautions: levels are never exact prices, and none is permanent — he deletes one once price has chopped across it, saying it has lost its value. The best are those price has used as both support and resistance.

Editor's note — the standard name for role reversal The ceiling-fan idea has a textbook name he never uses: **polarity**, the support-resistance flip, described in Edwards and Magee long before charting software. His own stated reason is that the market's memory of what happened at a level persists .

3.3 Zone, area of interest, demand and supply

The biggest shift across six years is from **line** to **zone** — the thick area the market has hit repeatedly, preferred because the market visibly reacts on a thick zone. In 2022 it was mild: a line is "a little inaccurate" but still works, and the trigger for switching is a messy chart, turning points clustering at slightly different prices. By July 2026 it is an instruction: stop drawing lines and rays, use boxes. A dated evolution, not an inconsistency.

Area of interest (AOI) is the umbrella term: in 2020 a place where there is a special level; in 2026 an area from which the market reacts and *may* turn — may, not will — or loosely any interesting area marked with a rectangle. The rule attached: never trade without one, and only then apply price action on top of it; it is abbreviated elsewhere as **POI**. **Demand** and **supply zones** are the zone-shaped version, also called order blocks: below price is demand, above is supply; support is the demand zone, resistance

the supply zone. Behaviourally, a supply zone is the swing from which the market has repeatedly fallen.

3.4 Structure: swings, trend, pullback, consolidation

The **swing** is the base object: one low joined to one high, also called a range. Highs and lows are counted by candle colour, not by eye — a high counts only once a red candle forms after a green one, so an intermediate high that merely looks highest goes unmarked.

An uptrend is higher highs and higher lows, stated the same way in 2021, 2022 and 2026; a downtrend is lower highs and lower lows. Neither may be called until the pair has clearly formed.

Pullback, correction and corrective wave are one term — a move against the main trend. The market never rises in a single go: high, shallower pullback, another high, his "zigzag theory", which he likes a lot. The constraint: the corrective wave must always be smaller than the impulsive one, and if it goes further, the move was not impulsive. **Consolidation** is the alternative — sideways, one step back before a big move; an old consolidation area becomes a support zone later.

The structure count varies by year: three movements in 2020; a 2021 taxonomy of impulse-correction-impulse, the same with a consolidation (the flag), and three impulses back to back, only about 10% of the time;

two structures in 2023; two *states* in 2024; three shapes in 2025. Consistent in substance — trending and ranging — but never reconciled. While price is inside the established high-low range, he says, nothing can be said about direction.

3.5 The trendline

A **trend line** touches the successive swing points of a trending move. Levels come in exactly two kinds on this basis, trend and horizontal, the trend level being the one that tells you whether the market is in an uptrend or a downtrend. The usage rule is asymmetric: trend lines for trending markets, horizontal lines for range-bound ones — but horizontal lines work everywhere, trends included. Touch points prefer body over wick, as with horizontal levels, because the close is the most important part of OHLC and is made on the body; hold both if the wick is small, body alone if it is long. Keep TradingView's magnet feature off.

He is deflationary about the tool: a trendline by itself does nothing — what matters is the action you get at it — though a break of the trend line tells you the trend has changed, a claim Chapter 6 shows him heavily qualifying. **Confluence** enters here: geometrically, where a trendline and a horizontal line meet; by timeframe, the same reading appearing on two. Either way more than one reason lands on the same price, and the more confluences, the greater the quality of the trade.

3.6 The renamed vocabulary

He treats smart-money terminology as relabelling and says so while teaching it: **break of structure is a breakout of some level**, change of character** a trend change. Properly, BOS is price breaking the previous high to create a higher high after a higher low; CHOCH is a rejection making a new low after a break of structure. **Liquidity** is where the orders are — people's targets and stop losses at a level — split into **external** (outside the structure, at the extreme highs and lows) and **internal** (inside the range). A **trap** is the market breaking a prior level and then failing there, equated with a liquidity sweep. Chapter 4 gives these their conditions.

3.7 Who is in the market

The participant vocabulary is the most stable material here, unchanged from 2020 to 2026: retail traders, high net-worth investors, and institutions, institutions dividing into FII and DII. Retail is anyone new, trading with ten rupees or a crore. Neither exchange nor broker sells you the share — the transaction is between trader one and trader two, routed through them.

Hence why price moves. He rejects the naive version: the number of buyers and sellers never increases or decreases — an accounting identity, since every executed trade has one buyer and one seller. Price rises because buyers become willing to pay more, taught by bidding an apple

up from Rs 10 to Rs 15, and falls when a large seller drops his asking price to offload quantity. What varies is aggression — though elsewhere he gives the looser version, buyers increase and sellers dominate, which sits awkwardly with his own correction. Both are in the record.

What he doesn't say about this

- **No rule for how wide a zone should be.** Switch from line to rectangle when turning

points cluster messily and the market reacts on a thick zone — but no width in points, ticks, ATR multiples or percentages.

- **The touch count is a range, not a number.** Two,

three-minimum-four-better, three-to-six counted live, with no rule for which applies where.

- **He does not reconcile his own structure counts.** 2020, 2021, 2023, 2024 and 2025 each give a different taxonomy, none treated as a revision.

Chapter summary

- Two drawing tools do the whole job at beginner level — trend line for angled levels,

horizontal line for flat — with Fibonacci and pitchfork reserved for experienced traders.

- Support is where price repeatedly stops falling, resistance where it repeatedly fails to

rise, but neither is a property of the level: direction of approach decides the name.

- A broken level reverses role on the retest.
- His level vocabulary moved from lines to zones, ending in an instruction to use boxes.
- Demand and supply zones are the same thing widened.
- An uptrend is higher highs and higher lows, a downtrend the reverse, and neither may be

called until the sequence is clear.

- Pullback, correction and corrective wave are one term, and the correction must always be

smaller than the impulse.

- SMC vocabulary is relabelling: BOS is a breakout, CHOCH a trend change, order block a

demand or supply zone.

- Levels are never exact and are deleted once price chops through them.

Try this

The first skill is marking levels: mark them on the bigger timeframe, then look on the smaller timeframe at where the liquidity was.

1. Open one instrument on the 4-hour chart — he uses it purely to mark important levels, and levels must be drawn on at least the hourly timeframe. Switch the magnet feature off. 2. Draw a level wherever price has visibly bounced from the same place at least twice, marking from bodies rather than wicks. Where turning points cluster at slightly different prices, use a rectangle instead. 3. Stop at four: four high-quality 4-hour levels are enough, and never dirty the chart. Record each one's touch count and whether price has used it as both support and resistance, the kind he rates highest. 4. Come back after a week and delete any level price has chopped across, on his rule that it has lost its value. Which survived — not the trades — is the output of the exercise.

Chapter 4 — Smart Money, His Way

In this chapter: the smart-money-concepts layer he teaches as a distinct system — liquidity, sweeps and traps, order blocks, fair value gaps, confluence — held together by his own repeated claim that none of it is new, only price action wearing harder English. Includes a translation table for readers arriving from ICT or SMC material elsewhere.

4.1 His position: SMC is price action with the words swapped

Asked whether he follows smart money concepts, he answers that he follows price action, and that SMC is itself made out of price action. SMC renamed existing ideas and made the English harder; price action is the country, SMC a state inside it. He calls the price-action-versus-SMC debate a false opposition.

The translation is mechanical. A **break of structure** is a breakout; a **change of character** is a trend change; a **liquidity grab** is the market going into a trap area and coming back; an **order block** is a supply or demand zone under older vocabulary. The rename he returns to most: his

trap is what others call a **liquidity sweep** — not a hard concept, just the trap he's drawn.

He refuses to rank SMC against other methods; what matters is which one you understand, and mixing them all leaves you unable to do anything. ICT he rates a bad starting point for beginners, being over-complicated. He claims the concepts work on Nifty and Bank Nifty, gold and forex alike, across timeframes, hedging that they work only "if you apply it" and with self-control.

Editor's note — where this vocabulary came from He treats the SMC terms as recent relabelling and notes they weren't in the older books. The accumulation/distribution framing he uses is Wyckoff's, from the 1930s; order blocks, fair value gaps and break of structure were popularised in the 2010s by "Inner Circle Trader" material. The ideas do have older names, but the mapping isn't exact: "order block" and "supply zone" are drawn by different rules.

4.2 Liquidity: the load-bearing concept

Liquidity is how easily you can buy or sell something; technically, where the orders are. The version he trades is narrower: where other traders' stop-losses or targets sit. Hence the slogan — liquidity is money, because placing an order commits money.

External liquidity sits outside the structure at the extreme highs and lows; **internal liquidity** sits inside the range. External trades are more sure-shot; internal ones are also good provided the level has had two or three touches — that requirement attaches only to the internal case.

The mechanism rests on one observation: **a stop-loss is an order on the other side**. A short seller's stop is a buy order; a buyer's stop below support is a sell order. So an institution that can't fill its size pushes price into the liquidity area first, collects the forced flow, then executes — waiting rather than punching orders in, with the small breakout dragging in fresh retail buying on top of the stop flow. He says roughly seven in ten of his trades run on this one idea.

His own limits on it: knowing where the liquidity sits is useless alone, since everybody knows that much; liquidity does not sit only at highs and lows; and a pool is not a guaranteed reversal, since a large enough new order can match against it and drop the market.

4.3 The trap, which is the sweep

A trap is price breaking a level and coming back inside it: below support and back above, or out of a level and then a close back inside. A **bear trap** is a fall below a level closing back above with a solid green candle; a **bull trap** a breakout that invites the bulls in, then a red candle that traps them. Under the SMC name this is a liquidity sweep — resting liquidity cleaned

out so stops trigger, get absorbed, and price moves the other way. His rules:

- **A close, not a wick.** The trigger is a *closing* back inside the level, not a poke; he draws levels from candle bodies and says not to act on wicks

at all.

- **The break should be small** — that's what distinguishes a sweep from a genuine

breakout.

- **It should be quick** — back inside within roughly forty to fifty minutes, or four

to five candles on the 5-minute.

- **The level should have history** — for a sell-side trap, a top where the market has

already failed once.

- **Stop placement:** on the high of the candle that made the fake high, or below the

level where the trap formed — his "logical stop."

4.4 Why the trap and not the breakout

Most breakouts fail, a figure he once put at 65%, and the break converting into a trap is what makes plain breakout trading a loser most of the time. He doesn't trade direct breakouts or direct reversals of the previous day's levels; he waits for a trap. Trap trading is the best of the four price-action styles he names — breakout, reversal, trap and retest — and his biggest trades and most of his money came through it. The best way to grow a small account is to become a trap trader, entering where the maximum number of stop-losses are hitting, which needs a lot of patience.

The market has changed since 2018-2021 and traps far more, because everybody knows the classical concepts; reversals that used to run straight up now break down first, hence his insistence on confirmations. In a 2025 Q&A he agrees that support and resistance don't work in today's market — which sits badly against the level-marking his own trap setup depends on; read it as emphasis of degree, not a retirement of levels. Traps work very well in forex while breakouts also work in the Indian market; in one 2026 video he advises *against* the concept in crypto, reversing his own opening claim in the same video, because so much trap trading runs in Bitcoin that even the trap gets trapped.

His entry instructions conflict: in 2026 a break closing back inside must be shorted quickly and directly, waiting for a retest being a mistake *in this case*, yet elsewhere his trap entry stacks four things including a retest of the swept level. Read it as conditional — the direct version is the one he calls best, the retest variant a slower entry he also takes.

4.5 Order blocks

An order block is the small candle immediately before a very large impulsive candle, marked from that candle's high to its low, wick included, and extended forward as a zone; its colour doesn't matter. A candle that large means institutional money was involved, because retail cannot move the market that much — the aftermath of an imbalance in which limit orders were left unexecuted, so the market returns to deal with them. Three validation rules, the first most important:

1. **The wick must not have been completely inserted into the block** — once that happens the zone is violated. 2. **There must be a gap between the first and third candles** of the three-candle sequence; if it fills completely, the block is cancelled. 3. **The market should carry on ahead** rather than finishing the second candle immediately.

He restricts them to higher timeframes: in 2024, 15-minute, 1-hour and 4-hour; by 2025 the floor rises to at least 30 minutes, with 1-hour and 4-hour best and daily better still. When price returns into the block there's a high chance — a probability, not a certainty — that it continues in the original direction, but he requires the market to enter and then *turn* rather than trading the arrival. Stops go below the block for a long. The advanced usage is to mark the block's 50% level and treat that midpoint as the main level, requiring price to touch it before planning anything, because perfect levels can't be marked in forex and gold where quotes differ between brokers.

4.6 Fair value gaps

A fair value gap is the space between the first and third candles of a three-candle sequence built around a very large middle candle — an imbalance between buyers and sellers. Wherever there's a gap there's also an order block, because the gap can only form for the same reason.

A measurement inconsistency worth knowing about. In September 2024 he defines the gap wick to wick *or* body; in August 2025 the body; in February 2026 he's back to wick-to-wick. The structure never varies, but readers get different boxes depending on which video they follow.

The quality filters matter more to him than the definition. The middle candle must be big by *body*, not wick; the outer two should be small, and gaps where they're also large don't work well. Trade only gaps that come with large candles, because that's the only way results are good — which is his whole complaint against indicators: they mark gaps everywhere, people trade those and lose, then conclude the concept doesn't work.

The routine is stable across two years: mark the gap on the higher timeframe — "always" the 15-minute in 2024, later 1-hour — then drop a timeframe to execute when price returns. He draws a 50% midline and builds his **premium/discount** rule on it: on a buy, entry below the 50% line; on a sell, above it — the stated reason is stop-loss size. He doesn't enter on the displacement candle itself, whose stop would be too wide, and arrival is not the entry: he requires a confirming candle, which in the 2024 version must come *out* of the gap. Stops go a little beyond the gap and its wick, with 50% of the box offered interchangeably as an

alternative; targets are 1:1.5 or 1:2. Filled gaps get deleted, only unfilled ones extended forward.

4.7 The inverse fair value gap, and the gap's demotion

The **inverse fair value gap** is what he trades when the setup fails: after a gap is violated or mitigated, price returns to the same zone from the other side — "a fair value gap that has been broken," which he expects the market to retest. The violated gap keeps its box and midline instead of being deleted, which is the precondition for the trade; he waits for a confirming candle before entering the opposite way, with the stop below the confirming candle that failed.

His hedges are explicit: a good technique but not a 100% one — roughly six or seven trades out of ten on his own estimate, no backtest given — with viewers asked to backtest it themselves. From experience, the gap deceives you often: price enters, prints a green candle, then takes out the stop.

And he's demoted it. In a 2026 class he tells students, after using the gap to locate order blocks, to stop caring about fair value gaps from that day and trade only order blocks and sessions. He still uses gaps for profit-taking at a zone's first gap and as a trailing reference when a fresh gap forms below a running long. Read the arc as dated evolution: through

2024-early 2025 the gap is a standalone setup; from mid-2026 it's a locator and a management tool, and the order block carries the entry.

4.8 Confluence, and the "sniper entry"

Confluence is two things happening at the same place at the same time. As a procedure: build two or three favourite setups of your own and take the trade only when all appear together — order block plus moving average plus zone is his worked example. He applies it to data too: trade only when price action, the indicator, option open interest and FII data agree, and stay away when they fight. Confluence is his stated reason for sizing up.

The **sniper entry** is his named confluence template, trap and order block welded together: find a liquidity level, let it break, get a support after the break, enter on the reversal; restated in 2026 as the market hunting liquidity and then taking support where another support already exists — two confirmations. He reports specific results — a gold long booked for \$14,000, \$67,000 from a sniper entry combined with the order block concept — which are his own claims, recapped after the fact, not typical outcomes. He hedges here too: a two-factor confluence trade of his was still stopped out, and a pound trade he called the best confluence you could ask for lost anyway.

Editor's note — when stacked signals are not independent

evidence He treats each added factor as strengthening the case, and his own losing examples show the limit. Confluence only adds information when the factors carry *different* information: an order block, a fair value gap and a supply zone all derive from the same impulsive move — he himself says a gap implies a block is there. Counting three views of one event as three pieces of evidence makes a position feel better supported than it is.

What he doesn't say about this

- **He gives no verifiable performance data.** The hit rates are his own estimates with

no sample: six or seven out of ten on fair value gaps, 70-75% quoted in passing, above 60% at 1:2 on the trap system from a 15-day walk-through. He tells viewers to compute these themselves.

- **The institutional story is inference, not observed order flow** — drawn from how his

own pending order behaves, not from order-book data.

- **He does not say which liquidity level wins when several are in play.** External is

preferred over internal, but for two close external levels, or a higher-timeframe level disagreeing with an intraday one, he gives examples, not a rule.

- **He does not reconcile "this is nothing special" with teaching it as a system.** He

says SMC confers no status and that what works turns out to be basic, with no levels or sweeps or ICT concepts — while building most of his 2025-2026 walkthroughs on exactly this vocabulary.

Chapter summary

- His stated position is that SMC is price action with harder English:
break of

structure is a breakout, change of character is a trend change, a liquidity sweep is what he calls a trap, and an order block is a supply or demand zone.

- Liquidity, in his working definition, is where other traders' stop-losses and targets

are sitting; it splits into external liquidity at the extremes and internal liquidity inside the range, with external preferred and internal requiring two or three touches.

- The mechanism is that a stop-loss is an order on the other side, so a large buyer

needs stops hit to get filled — which is why price is pushed into a liquidity area before the real move.

- His core setup is the trap: a break of a level followed by a *close* back inside, on a

small break, with the level drawn from candle bodies. He doesn't trade direct breakouts, because most breakouts fail.

- An order block is the small candle before a large impulsive candle, marked wick to

wick and extended forward; valid only if its wick hasn't been fully inserted, and restricted to higher timeframes.

- A fair value gap is the space between candles one and three around a large-bodied

middle candle; he trades only large-candle gaps, marks a 50% midline, requires a confirming candle, and deletes gaps once filled.

- The inverse fair value gap is his trade *after* a gap fails: keep the violated box,

wait for price to return, enter the other way on a confirming candle.

- Confluence is two or three of his own setups landing in the same place, and it's his

stated reason for increasing size — while he shows confluence trades that still lost.

- The hedges are his own and part of the method: nothing works 100% of the time, the

concepts work only if applied with self-control, and he asks viewers to backtest his figures rather than believe them.

Try this

Build the verification he asks for, on one instrument, before trading any of it. On a 15-minute chart, mark every fair value gap over the last three months using only his quality filter — small first and third candles, a very large middle candle by body. Put a 50% line through each and record whether price filled to that line, filled completely, or never came back — the three outcomes he says price action decides between. Then walk it day by day, with the decision recorded before you advance the chart. Re-walk the same days requiring his entry condition — a confirming candle at the gap or the 50% line — and compare the two passes against the six or seven out of ten he estimates.

F4.1 — His trap-entry decision tree, reconstructed from the three conditions he states in sequence. This is a schematic of his stated rule, not a claim that he draws it this way himself.

F4.1 — reconstructed from the three conditions he states in sequence: the break must be small, price must close back inside the level rather than merely wick into it, and the close-back must happen within roughly 4-5 candles or 40-50 minutes. Entry is on the close-back-inside candle, stop beyond the swept level. This is a schematic of his stated rule, not a claim that he draws it this way himself.

F4.2 — a schematic three-candle pattern, not a real chart. Candle 1 is small, candle 2 is the large displacement candle, candle 3 is small again. The shaded band is the price zone candles 1 and 3's wicks never touched — his fair value gap, with its 50% midline. The order block is candle 1's own high-to-low range.

F4.3 — SMC/ICT vocabulary translated to his price-action terms

SMC / ICT term	His term
Break of structure	Breakout
Change of character	Trend change
Liquidity sweep / grab	Trap
Order block / breaker block	Supply or demand zone
Fair value gap	Imbalance left by a large candle

Chapter 5 — The Setups

In this chapter: the four named entry families he keeps coming back to — breakout, retest, the trap, and the opening range — with the conditions that qualify each one, the conditions that disqualify it, and the rule that governs all of them: fewer setups, more selectively taken.

5.1 Four families, and why the list keeps shrinking

The count moved as his teaching matured. In December 2021 he says there are only two types of trading, breakout and retest, then corrects himself in the same session to three — breakout, reversal, retest. By January 2026 the list has settled at four — breakout, reversal, trap and retest — presented as complete. This chapter covers breakout, retest and the trap in detail, plus the opening range, which is the most heavily specified container he puts those entries into. Reversals belong with levels and patterns, in [[Ch. 6]] and [[Ch. 7]].

What matters as much as the list is the instruction attached to it: hold a deliberately short list and refuse everything outside it. In August 2024 he dates the change that turned his equity curve upward to cutting from seven or eight setups down to three or four, with the reason being knowability — the fewer setups you work on, the more knowable their past win rate

and win size. In April 2025 he hands students a four-setup list and tells them to forget the other patterns, for now.

A general prohibition governs everything below: no technical signal, no trade, and never trade without an area of interest — only once you have one do you apply price action on top of it. The pattern tells you what; the level tells you whether.

Editor's note — what a "setup count" is actually measuring He ties the setup limit to knowability; the statistical reason he doesn't spell out is sample size. Two hundred trades a year across eight setups gives roughly twenty-five observations each — far too few to separate a 45% win rate from a 55% one, since the standard error at $n=25$ is about ten percentage points. Concentrate the same trades into three setups and each gets sixty-odd, still thin but at least beginning to distinguish.

5.2 The breakout, and its filters

His definition is plain: price arrives at an important level from below, touches it, and breaks through — a breakdown the same thing direction-flipped. The mechanism is that short sellers' stops sitting above resistance trigger as buy orders, part of what creates the breakout.

The load-bearing part is the filter set, because he is consistently negative about the unfiltered version: most breakouts fail, and in 2020 he puts a figure on it — 65%.

Filter one: prior consolidation. Rule one is never take a breakout unless there's consolidation before the break; breakouts without it should be ignored even when they work, since the failure rate produces more losses than a beginner can bear. His self-labelled approximations: without consolidation a breakout fails about five times in ten, after consolidation it passes about eight in ten. How much is enough varies with instrument and timeframe — at least five sideways hours for an intraday forex strategy; two days for a box consolidation on the index. The unit changes; the requirement does not.

Filter two: repeated prior tests. It's a breakout when price finally breaks a level after being resisted there two or three times, with continuation on that multi-touch structure put at 60-70%, explicitly hedged and explicitly not 90%. A level only counts as key support or resistance with a minimum of three touches, four being better.

Filter three: where the breaking move started. The check is the distance of the move's starting point from the break point — the closer start being more likely to break — explained as a race between runners starting from different points. The consequence is a skip rule: he passes when the breakout has already run away from the level, the train has left the station. In 2026 he softens the requirement — either a pullback or a consolidation before the break is enough, both aren't required.

F5.1 — reconstructed from his four stated conditions for treating a breakout as tradable rather than as a chase. Sources: [EV-vr6ZsreYRAI-19] [EV-ufsJQ4wq-Vg-14] [EV-fjQk4Zs8bmY-04] [EV-Rf5u-B9nWt0-02]. This is a schematic of his stated rules, not a claim that he checks them in this exact order or draws them this way himself.

F5.1 — reconstructed from his four stated conditions for treating a breakout as tradable rather than as a chase: consolidation beforehand, at least three tests of the level, a move that starts near the level rather than an already-extended one, and a confirming close beyond it on the qualifying timeframe. This is a schematic of his stated rules, not a claim that he checks them in this exact order himself.

5.3 Confirming the break: closes and candles

The confirmation rule is a **close**, not a touch. A level is broken only once the candle closes beyond it, with the body closing beyond rather than a wick through. Which timeframe's close counts varies by strategy: at least the one-hour for a swing long, the 15-minute for an intraday index level.

He also wants the breaking candle strong — a "power candle," present on the 15-minute and not only the small chart — refusing the trade when it's weak or carries a large wick. The fat body with small wicks is the power candle, what the world calls engulfing; it has a job: the power candle is for breakouts, the pin bar for reversals.

5.4 What "never take a direct breakout" actually forbids

He says with force that you must never take a trade directly on the breakout, and in November 2025 goes further — breakout trading should not be done at all, softened to "very little" in the same breath. Yet he takes breakout entries frequently: immediately on a budget-day range break with a strong powerful candle, without waiting for a retest.

The reconciliation is definitional. The attached conditions make clear that "directly" means without the two qualifying checks — prior distance travelled, and a pullback or consolidation before the break — either one being sufficient. "Direct" means unqualified, not un-retested, and that's the only reading consistent with his own trade tape. One dated position should be flagged rather than folded in: in June 2026 he says the era of drawing a line and buying the break is over, while continuing to take breakout entries in the same period.

5.5 The retest: the entry he calls the safest

After a level breaks, price comes back to that same level and the entry is taken on that second test — the role flips, so broken resistance now acts as support. In one sentence: if the market converts a resistance into support, buy. The mechanism is trapped participants — traders who didn't use a

stop loss and are deep in loss exit at breakeven, so their supply appears exactly at the retest; on the other side a short seller exiting has to buy, which is why buying there is considered safe, hedged, since the level can still convert into a trap.

His pass/fail test is binary: if the old level acts as resistance again and price comes back down, the retest failed; if price goes up, it passed — a green candle being the pass. A red candle at the level in a bullish retest kills the setup. The tolerance is deliberately loose — price need not touch the drawn line exactly, and in the moving-average version anything within roughly 1% of the EMA counts.

Editor's note — the polarity principle, and where it comes from

The support-becomes-resistance flip is one of the oldest documented ideas in Western technical analysis: Edwards and Magee's *Technical Analysis of Stock Trends* (1948) calls it the principle of polarity. His stated mechanism — trapped participants transacting at breakeven — matches what behavioural finance calls the disposition effect. He reaches the same conclusion from the desk, and cites neither.

5.6 Risk entry or retest entry

The unresolved question is **whether a retest always comes**. In 2020 he states that whenever a breakout happens, a retest happens for sure. Elsewhere he says the opposite plainly — a retest is not necessary, the

breakout can simply run — and names the cost of insisting on one: a lot of the time there's no retest and the stock launches directly. By June 2025 the claim is scoped: always wait for the retest on the one-hour or larger timeframes, explicitly limited to those. This book reads the 2020 "for sure" as casual overstatement in a beginner video; treat the retest as likely and structurally useful, not guaranteed.

He resolves the trade-off with two entries: a **risk entry** on the break and a ****retest entry**** after the pullback, the choice depending on the type of trader you are — he calls the retest the perfect entry while still taking risk entries himself. Safe traders take the retest; only the experienced take the break entry. He also uses both, taking the breakout with half the position and adding the second half on the retest.

5.7 The trap: when the breakout is the bait

The trap is the inverse of the breakout, and in his later material the setup he takes most often. The definition requires a close, not a wick: price breaks out of the level and then gives a closing back inside it — the close back inside is what makes it a trap, the break alone is not. Both sides need closes: a close beyond, then a close back in.

The mechanism is order flow. Big sellers wait, and a very small breakout above the level triggers all the shorts' stop losses, making a large amount of buy-order liquidity available — he's explicit that the move which does

this is a small breakout, not a nice big one; retail traders seeing the small break add their liquidity too. The distinguishing feature is that price doesn't run far past the level.

Timing is applied strictly: a trap only counts if it's quick — back inside within about forty to fifty minutes, or four to five candles on the 5-minute timeframe. In another strategy the window is a clock time, before 11:45am, and a later return means the day is discarded entirely.

The trap material carries the chapter's strongest no-trade rules. On a strategy built on the previous day's high and low, he doesn't trade direct breakouts or direct reversals of those levels at all, since they aren't respected often enough; if price never closed back inside, he counts it as no trap and deletes the level; and on a day where neither level traps, he takes no trade, showing several such flat days across a two-week walkthrough. One execution note runs against the retest instinct: on a break that closes back inside, short quickly and come in directly — there's not that much time.

5.8 The opening range: waiting, the exception, and the 1% filter

The dominant position is **wait**. He tells beginners to watch the first 15 minutes rather than trade them, and in February 2026 gives it cleanly: do nothing for the first 30 minutes after the open and let the market build a range. On budget day the wait is longer: nothing until roughly 10:30 to

11:00, after which he marks the high and low of the range built by 11:00 and buys only on a closing-basis break of it, refusing a break even at 10:55.

The minority position is that **the opening drive is itself a setup**, permitted conditionally: you cannot enter in the opening drive like a gambler, but you can sometimes, with a built system trading strategy. Under those conditions he does take them, calling the first-candle version rare, since the market is very rarely sitting right at a top or bottom at the open.

The oldest fully-specified version is the **open-high-open-low strategy**, the first strategy that ever worked for him: do nothing for the first 15 minutes, draw two lines, buy whichever way the market breaks, with no retest required. Its first rule is a **range-size filter**: the range must be below 1% of price, with 0.6%, 0.7% and 0.8% good, and 1.2% or 1.5% absolutely untradeable — change the stock rather than adjust the trade.

The 2025 indicator-assisted ORB on US equities is the same idea with a cleaner number: the trade only forms if the opening range measures less than 1%, because a large opening range means the big early-morning move has already happened — the same logic as his distance-travelled filter. One further opening family doesn't depend on the first candle: the **gap trade**. On a gap day there are only two tradeable ways in — a breakaway gap or a gap fill — and if neither is available there's nothing to do.

5.9 Choosing between the setups on the day

Having several qualified setups doesn't mean taking whichever appears.

The day's remaining range. His first check is how much of the daily range is already used up, since the space left decides whether a trade is on at all. The ATR tells you which type of trade to apply that day.

Trend. However good the setup, if the trend is down, buying will only produce a loss.

Risk-reward as a gate. The minimum has drifted upward: a floor of 1:1 in 2020, 1:1.5 in 2021, and 1:2 or 1:3 named in 2025 as what people need to be taking. He's clear about the cost — a 1:3 trader gets fewer trades, maybe one setup every three days. The exception is the low-ratio, high-hit-rate setup he built for funded accounts, where the best win rate comes at 1:1 and stretching further drops it.

Confluence. Two or three things happening at the same place at the same time, and the more confluences, the greater the quality of the trade. He drops a stock when he gets confirmation from one source and not the second.

Expected frequency. A high-win-rate strategy comes only two or three times a week, not four or five times a day, and demands more patience. If you're ever in doubt, simply don't trade.

What he doesn't say about this

- **No measured statistics for any setup.** Every hit-rate figure here is his own

estimate — 65% of breakouts fail, eight-in-ten after consolidation versus five-in-ten without. No trade log, sample size or date range is published behind any of them; he tells the reader to backtest and verify above 50% himself.

- **No rule for choosing between two simultaneously valid setups.** He gives

selectors — ATR, trend, confluence, risk-reward — but no priority order when a breakout and a trap qualify on the same chart at the same time.

- **No definition of "important level" independent of judgement** beyond the

three-or-four-touch criterion.

- **Whether breakout trading is worth doing at all is unsettled in his later material.**

The November 2025 "should not be done at all, or very little" and the June 2026 "the era of drawing a line and buying the break is over" sit against breakout entries he continues to take and teach through the same period.

- **Costs are absent.** No brokerage, slippage, spread or tax figure appears in any

setup specification, so every win rate and ratio quoted above is gross.

Chapter summary

- He classes all price action into four entry families — breakout, reversal, trap and

retest — and says everything else sits inside one of them.

- A breakout qualifies on three things: consolidation before the break, a level tested

several times, and a breaking move that started close to the level; by 2026 he accepts either a pullback or a consolidation, not necessarily both.

- The break itself is counted on a closing basis, marked by candle bodies — never on a

wick through the level.

- "Never take a direct breakout" means never take one without the qualifying filters —

not that a break entry is forbidden; he takes break entries when the filters are met.

- A retest is price returning to a broken level, with old resistance now acting as

support; it passes on a green candle and fails on a red one, and that pass/fail is the only question he asks.

- The retest is not guaranteed: his 2020 "a retest happens for sure" is superseded by

his own statements that a breakout can simply run and that the retest is compulsory only on the one-hour and above.

- A trap is a break that gives a close back inside the level, quickly — within roughly

four to five candles or forty to fifty minutes on a 5-minute chart; on a trap-only strategy, no trap means no trade that day.

- The default at the open is to wait — nothing for the first thirty minutes — with an opening range under 1% as his primary filter, since a

wide one means the day's move has already happened.

- Setup count is itself a rule: he cut from seven or eight setups to three or four and

credits that with turning his own results around.

Try this

Backtest one setup, by hand, over years — not weeks. Pick one setup and backtest it quietly over two to three years of history, on whichever instrument you actually trade. His definition of backtesting here is not "checking what the data says" but taking a strategy with defined rules and manually extracting its trade-by-trade record — the rules have to exist first. His pass mark is a win rate above 50%, at which point that's enough to go and trade the setup — and if the data comes out poor, change the strategy rather than trade it.

F5.2 — The four setups compared

Setup	Trigger	Required prior structure	Confirmation basis	Disqualifier	Stated frequency/hedge
Breakout	Price arrives at an important level, touches it, breaks through	Consolidation before the break; level resisted 2-3 times first; break starts close to the level. By 2026, either a pullback or consolidation, not both	Close beyond the level, by body not wick; breaking candle a "power candle." Timeframe by strategy	No consolidation beforehand; move already run away; weak breaking candle	65% of breakouts fail; ~5-in-1 without consolidation vs. 8-in-10 after; not measured statistics
Retest	Price returns to a broken level; buy if resistance converts to support	Prior confirmed break, role flipped	Binary: green candle at the level is the pass, red is the fail; loose tolerance, no exact touch required	Red candle at the level in a bullish retest kills the setup	Not guaranteed — "for sure" in 2020, contradicted later; scope to 1H+ by 2025
The trap	Break out of a level, then close back inside it	A level with stops pooled beyond it, taken out by a <i>very small</i> breakout	Closes on both sides; must be quick — 40-50 minutes or	A break that returns much later doesn't qualify; no close back inside	No trap means no trade — several flat days shown across a

Setup	Trigger	Required prior structure	Confirmation basis	Disqualifier	Stated frequency/hedge
	— the close is what makes it a trap		4-5 candles on 5-min	means no trap	two-week walkthrough
Opening range	Break of the marked opening-range high/low after the wait period	A formed range, nothing traded before it; range itself must be small — under 1% of price	Closing-basis break of the marked level, no retest required	Range at or above 1% — untradeable, change the stock; break before the stated clock time	The open-high-open-low version "sometimes works, not exactly but almost"

F5.2 — a reader's-aid synthesis assembled from claims made separately across this chapter; he never presents the four setups as a table himself.

Chapter 6 — Reading the Chart: Structure and Levels

In this chapter: what he means by price action, how he decides which prices on a chart matter, how he draws them, how he reads trend and structure around them, and how he splits the work across two timeframes.

6.1 What "reading the chart" means to him

His definition of price action is deliberately flat: whatever action the price itself takes, read off a plain chart, with no indicator. Technical analysis he defines operationally as finding where to buy, where to sell, where to book the target, and where to cut the loss. Fundamental analysis is for investing, technical analysis for trading. In 2020 he says only two of TradingView's drawing tools matter — the trend line for a level at an angle, the horizontal line for a flat one — and if you can draw those two you need nothing else. Use as few indicators as possible.

The position is less absolute than the slogans. He keeps moving averages on his own charts alongside naked price, and by 2025 says he's not calling indicators bad, only that you should use a limited number — the mistake

is quantity, since with too many you can't see price at all. Every indicator is built from price data anyway, and using one doesn't disqualify you as a price-action trader. He concedes the term is useless until you say what inside it you're trading.

6.2 What makes a price on the chart important

Support is a level that repeatedly stops the market falling further; resistance is one it's repeatedly unable to rise above. Less ordinary is his insistence that the labels aren't properties of the level: approached from below a zone is resistance, from above the same zone is support. No level is born as either — the name depends on where price sits; your ceiling fan is your neighbour's floor. Hence role reversal: broken resistance acts as support on the return, and the reverse for broken support.

What qualifies a price is turning points: draw a horizontal line where the market turned, a ray at every such point being the beginner's first step. Levels are found by eye, by observing where the market tends to stop; no tool or calculation is needed. An area matters because price actually fell from there before, and that fall is the proof supply sits there.

Touches are how he grades a level, and his stated minimum varies. Two is the beginner's floor — price has visibly bounced from the same place at least twice — but twice-touched is only a possible area of interest, explicitly not a good one. Three is where he starts to trust it: a three-touch

area is very good and he'll trade the third and fourth touch; three touch points make a level major, one makes it minor. Elsewhere the bar for a *key* level is three minimum, four better. Read as a range it's consistent: two makes a candidate, three makes it tradeable, more is better.

Other things raise a level: a zone that has acted as both resistance and support; a consolidation, which becomes a very important zone; duration, as where roughly thirty four-hour candles held support before a breakout. Round numbers get their own place — Bank Nifty 43000 and Nifty 18000 as strong resistance — because heavy orders cluster there, placed by slower traders who forget them.

Editor's note — why tested prices behave differently He justifies a level mechanically: when a crucial level breaks the market falls suddenly because the stop losses under it trigger at once. The Swiss National Bank's 1.20 floor on EUR/CHF is the documented case — defended for three years, then broken in January 2015 with a roughly 30% move in minutes. Clustered orders make a level real and make its break violent; he never treats the case where the defender simply withdraws.

6.3 Line or zone, body or wick

His long-run drift is from lines to zones. In 2020 the horizontal line is the whole technique; by 2022 he prefers a box because the line is a little

inaccurate, though the line still works; by 2026 the instruction is to stop drawing lines and rays and use boxes, a line being something he now uses very rarely. The market visibly reacts on a thick zone, a zone being the thick area price has hit repeatedly whereas a support line is a single price. The trigger for widening is messy data: when turning points cluster at slightly different prices he switches to a rectangle and trades the breakdown of the zone rather than of a level. Demand and supply zones are the zone-shaped version of support and resistance, also called an order block.

Body versus wick is where his material is genuinely inconsistent. The dominant instruction, repeated for six years, is body: levels are drawn from candle bodies, never wicks; he always draws on bodies and marks day highs and lows on a body basis. The close is the most important part of OHLC and is made on the body, and the body shows agreement between buyer and seller while the high and low are extremes where someone tried and failed.

Against that stand exceptions. A level still works if the wick falls into it; the body is only a preference. For a gold strategy he says outright to draw the day's high and low from the wick. Most sharply, inside a single 2026 video he draws a double-top neckline by the wicks because that's how the market moved, then later says to draw by the bodies and ignore the wicks entirely. His most honest formulation is the late one: he sometimes draws on the body and sometimes on the wick, and what you must do is compare like with like — wick against wick, body against body. To students who object that price didn't touch the line exactly: make it touch, and don't

trade with that fussiness — levels are never exact prices, because price will betray a precisely drawn level.

6.4 Which levels to keep, and which to throw away

An over-marked chart is a source of losses. Never dirty the chart: mark only the levels that matter for where price actually is. He deletes old drawings, keeping the view dynamic, and deletes a level once price has chopped across it. He blames overtrading on marking levels on the 5- and 15-minute charts, which produces too many; four high-quality 4-hour levels are enough. Recency is the other filter: levels must be drawn close to recent price action, forgetting everything older. A trendline is useless once price has travelled far from it, and messy areas are ignored in favour of an identifiable phenomenon such as a retest or double top.

Against recency sits a category marked by convention. The previous day's high and low is his third method of marking levels, and in one gold strategy the most important position on the chart, seller pressure above and support below. He also marks the current day's running high and low, listing current day high and low with previous day high, low and close as reference points. The timing is practical: at the 9:15 open you have no current-day levels, so you mark the previous day's; coming in around 10am you mark the current day's and trade their breakout, because by then the market has made its intraday level on the 5-minute.

The reasoning is order-based. Traders who sold at the previous day's high have stops just above it, so they defend the line, and if it breaks the move should be fast; a break below the previous day's low grabs the defending buyers' liquidity before price returns above. Liquidity is people's targets and stop losses sitting at a level, and it doesn't sit only at highs and lows. An unactivated level is carried forward, not discarded, and he sets alerts rather than watching charts. The discipline tying it together is absolute: never trade without an area of interest; only then do you apply price action on top of it.

6.5 Trend and market structure

His model has three states: uptrend, downtrend, sideways, sideways not really being a direction. An uptrend is higher highs and higher lows, a downtrend lower highs and lower lows. For swing and positional horizons he adds a confirmation test: no uptrend until a clear higher high and higher low has formed, no downtrend until a lower high and lower low has. Markets don't travel in straight lines — a high, a pullback to a shallower low, another high — which he formalises as impulsive and corrective waves, pullback and correction being synonyms. One invalidation rule: the corrective wave must always be smaller than the impulsive one, or the move was not impulsive. A fall inside a strong uptrend is a pullback, not bearishness; markets fall fast but rise slowly, so don't expect a breakout to continue straight up.

His default is unambiguous. Trend is the number one consideration; if a trade isn't with the trend, wait. Trading against it is flatly a mistake, for reasons of risk-reward; in one forex video the floor is 1:1.5 counter-trend while with-trend trades go to 2, 2.5 or 3. Entry is at the pullback, not the extension — buying at the extended point is the worst position to buy, and in an uptrend he enters only at the higher low. The hedges matter: nobody can tell you where a trend ends, and he can't call the start either; shorting a double top or head and shoulders won't work in a strong trend until a retest has happened.

One horizon suspends the rule. For intraday traders there are no three trends and no three phases — be totally neutral biased, the greater trend doesn't matter, because even a trending market doesn't only go up. That sits in tension with "always with the trend," reconciled only by horizon: a 4-hour pullback can be a complete trend for a fifteen-minute trader, and the trend is taken from your own analysis timeframe, so Bitcoin can be in a daily downtrend while he trades the hourly upward.

6.6 Two timeframes: one for analysis, one for action

The split is the backbone of his method and one of the few things he states identically across six years. Entry and exit are taken on a small timeframe but the market study is done on a bigger one; HTF is used only for analysis, LTF to take action. A trade never develops in five minutes.

Levels are drawn on the higher timeframe, candle patterns read on the lower, and *where* a pattern is forming is decided on the higher.

The selection rule is a mapping from holding period, not a fixed pair; the single criterion is whether a timeframe gives you enough candles to trade. Match the analysis timeframe to the unit of your holding period and act one step below: month to week, week to day, day to 4 hours, 4 hours to 1 hour, 1 hour to 15 minutes, 15 minutes to 5 minutes. The rows: intraday, 15 minutes and 5; short swings, 1 hour and 15 minutes; forex holds of three to ten days, 4 hours and 1 hour; positional, weekly and daily; investing, monthly and weekly. Session length modifies it: the daily candle is respected in stock markets because the market opens about six hours and closes each day, whereas forex closes only on Friday night, which is why the 4-hour works better there.

The intraday pair he names varies more than any other number in his teaching: 15-minute analysis with 5-minute action, 1-hour levels with 15-minute planning, 5-minute and at most 15-minute — each stated inside a particular strategy; the stable content is the *structure* — one timeframe up for context, one step down for the trigger, the drop being what keeps the stop loss small.

He states a reliability gradient: the higher the timeframe the more you can trust it, the lower the more traps, including false support and resistance. Levels must be drawn on at least the hourly, and he respects only higher-timeframe levels. Sometimes there's no point going down at all: while price is inside a box you're inside the same box on any timeframe. A 15-minute trader looking at the hourly is already messed up — yet ignoring

higher timeframes is also listed as an intraday mistake. His resolution is to pick your analysis timeframe deliberately and stop looking above it.

6.7 Confluence: when a level is worth acting on

Confluence is two or more independent readings landing on the same price — a resistance on both the 4-hour and the 1-hour. The more confluences, the greater the quality of the trade; agreement between big and small timeframe is the best quality a trade can have. He's specific about the pairings that count: a price-action level plus a moving average at the same price rates the level more highly, and he only adds to a position where the two coincide. His best intraday opportunity is price action where an intraday level and a previous-day level combine; setups at either alone he skips as traps.

The mirror rule is that missing confirmation means standing down: confirmation from one source and not the second, and he drops the stock. He picks the direction with fewer barriers. He notes the 4-hour and 1-hour often conflict — the honest version of the rule since a filter always satisfied would filter nothing. Pattern recognition is subordinated to location throughout: patterns should only be acted on at an area of interest, a candle's placement matters more than its shape, size or colour, and the zone is more powerful than the candle, with candle confirmation needed only after the level. That ordering — level first, candle second —

is the load-bearing connection to the pattern material that follows in [[Ch. 7]].

Editor's note — confluence only helps if the sources are

independent His examples pair genuinely different evidence: a price-action level with a moving average, a 4-hour reading with a 1-hour one. The unstated condition is independence — a 20 EMA, a 21 SMA and a 20-period Bollinger midline give three confirmations worth one signal, being near-identical transforms of the same closes. His strongest pairings avoid this by construction, but a reader could satisfy his rule and gain nothing.

6.8 What counts as broken

Because his entries, invalidations and targets all reference levels, when a level has given way carries most of the weight, and his answer is consistent: on a closing basis. A level is broken only once the candle closes beyond it; an open or a wick beyond doesn't count. He buys when the market breaks the marked level and gives a close, not on the break alone. The same test applies on exit, and the invalidation rule is stated in these terms: mark the level in advance, and if the market closes beyond it you close the trade and accept it. He adds quality tests on top: the break must come with power — a power candle outside the zone before acting — though a big candle confirms only if the level was important. His three qualities of a good breakout: the market consolidated a little beforehand,

the level had been tried and failed several times before the successful break, and the move began close to the level rather than far from it.

Against a straight break he prefers a retest as a default: they always try to trade the retest rather than the breakout, retests being the best entries. He defines it plainly — price breaks a resistance, returns, and the old resistance now acts as support — and on the 1-hour or larger says always wait for it. He never trades the first touch of a level: the first fall can't be traded because nobody knew in advance it would fall there, and buying just because price hit support is a mistake, since the level can still break. Two loosening survive: in a retest price need not touch the drawn line exactly, and the retest itself isn't compulsory; and where a level has already deceived him he marks an additional zone rather than deleting it — though no zone is reliable forever, because the market keeps changing its behaviour.

What he doesn't say about this

- **How to choose between conflicting timeframes when both are your own.** The 4-hour

and 1-hour often conflict; the higher timeframe's point of interest overrides the lower-timeframe break direction; an intraday trader facing a

5-minute uptrend against a 1-hour downtrend should stop looking higher. No rule decides which response applies.

- **Body or wick, decided.** He instructs body in most videos and wick in some, changes

convention inside a single video without acknowledging it, and finally offers only compare-like-with-like. A reader wanting one convention must choose it themselves.

- **Whether levels still work.** In a 2025 video he agrees that support and resistance

don't work in today's market and tells viewers to learn newer advanced concepts — directly against advice earlier in the same video about mastering zones and levels.

- **Any measurement of how often levels hold.** He gives loose global figures —

technical analysis at roughly 70-80 percent, distinguished from a strategy's win rate — but no hit rate for any level type, touch count or timeframe.

- **Which data feed to trust.** The exact level number changes between brokers and

exchanges, and in 2026 he says his biggest mistake had been studying the retail gold chart because it's a fabricated price — without revising the levels taught earlier.

Chapter summary

- Price action is whatever the price itself is doing read off a plain chart, and

technical analysis is the chart work that tells you where to buy, sell, book and cut.

- No level is inherently support or resistance: direction of approach decides the

label, which is why broken resistance becomes support on the return.

- Levels are drawn at turning points, and their weight comes from how many times price

has been turned away — two makes a candidate, three makes it tradeable, more is better.

- He has moved from single lines to boxes and zones, using a rectangle whenever

clustered turning points make one clean line impossible.

- Levels are mostly drawn on candle bodies, though he keeps exceptions and finally

settles only on comparing like with like.

- Keep the chart clean: mark only what matters near current price, keep levels recent,

and delete a level once price has chopped through it.

- Trend is higher highs and higher lows, or lower highs and lower lows; markets move in

zigzags, so entries belong at the pullback, not the extension.

- Analyse on a higher timeframe and act one step below it, with the pair chosen from

your holding period and the candle count it gives you.

- Quality comes from confluence — the same reading at the same price from two

independent sources — and a missing second confirmation is a reason to drop the trade.

- A level is broken only on a candle close beyond it; a wick or open through it doesn't

count, and the preferred entry is the retest rather than the first break or first touch.

Try this

He sets this as class homework himself. Take one instrument you already follow and mark horizontal levels on it twice — once on a smaller timeframe and once on the bigger timeframe, including the daily. Draw a horizontal ray at every point from which the market turned, working only from the price already printed to the left of your cursor and explicitly not looking at what came afterwards. Order the work as he does — support and resistance lines first, and only then look for whether a pattern is forming. Then apply the check he applies before trading: on the daily, is the instrument at an interesting level, meaning at a breakout or a retest? Anything that isn't, he skips.

Chapter 7 — Chart and Candlestick Patterns

In this chapter: what a single candle tells you, the very short list of candle types and chart patterns he keeps, the neckline rule that governs almost every pattern entry, what makes a candle good enough to act on, and how much weight he puts on a pattern at all.

[[Ch. 6]] covered where a level goes. This chapter covers the shapes that form *at* those levels, all subordinate to one rule he repeats in almost every teaching video: candlestick and chart patterns should only be acted on at an area of interest, and are of no use away from an important level.

7.1 Patterns are the last thing he looks at, and he says so

Candlesticks carry the *lowest* priority in his system — the candle is the last thing considered when deciding buy or sell; confirmation comes after bias and levels. Placement matters more than shape, size or colour, judged against market structure rather than in isolation. A signal that forms "in the air" is not to be taken.

The rule has an origin: a trader who kept buying every bullish engulfing candle and losing, where the answer was location. An inverted hammer at a low sends the market up even with a red body, and the same shape at a top is bearish.

Where the candle *does* work is at ambiguity. When a level has possibility on both sides, the candle tells you what will happen. The candle is not the reason for the trade — it's the tiebreaker and the trigger.

Pattern-*naming* is a beginner habit — a double top should be read as strong resistance being confirmed again rather than named. What he checks is breakout quality: multiple tests, consolidation, the move starting close to the level, which matters more than finding the chart pattern. The textbook classification into bullish, bearish and continuation he calls useless, and where no clear pattern is visible, don't overwork your brain looking for one — just mark the levels.

7.2 What a single candle is, in his reading

A candle is exactly two things, the thin wick and the thicker body — body is open to close, wick is high to low, green up and red down. Candles are the bricks out of which patterns, structure and trend are built.

The interpretive principle is single and unchanged for six years: the wick shows where price does not want to go — a lower wick means the market

doesn't want to go down, an upper wick that it doesn't want to go up. The rejection is read *opposite* the wick, the image being a pin pricking the hand; the longer the wick, the better the story. The body is the opposite evidence — control and power belonging to whichever side the colour indicates. His reason for weighting body over wick is the [[Ch. 6]] one: open and close show agreement between buyer and seller, while high and low are extremes where someone tried and failed to sustain price.

Two smaller readings recur. A candle with wicks on both sides gives no signal at all, even if green; when it's ambiguous you do nothing. And while a hammer is still forming it looks like a red power candle — only the close turns it into a hammer, the reason for the close-basis discipline in 7.4.

7.3 Three candles, and the renaming

Only three candlestick types are worth knowing. The formulations vary, the substance does not: power, rejection and confusion; a pattern only ever tells you reversal, continuation or confusion; in 2024, engulfing, hammer and doji, what he says he actually uses.

He renames the two actionable types, substituting his own vocabulary deliberately to make it easier for beginners. The fat-bodied candle with small wicks is the **power candle**, what the world calls engulfing — read as the market making a fresh start with one side winning and breaking out. The ****rejection candle**** is the hammer and its inverted mirror, a tail

below and body above at a low; its other name is the pin bar. Power candles are for breakouts, rejection candles for buying lower down after a fall.

The list he tells students to *stop* learning has grown. In 2022 he still allows five — morning star, evening star, shooting star, hammer, engulfing — while telling beginners elsewhere not to learn the hundreds available. By 2023 it's bullish engulfing or the tall-wick rejection candle and nothing else; by 2026, keep power and reversal and don't learn evening star, shooting star or hanging man at all.

The **doji** is its own category: never a confirmation and never a trade, only a hint a reversal may have come, created when price goes up and loses, goes down and loses, net output zero. Its one use is sequential — after a clear up move, a doji then a red candle is a super trade to sell, the evening star. He shorts on the candle after the doji, never the doji itself.

One definition does not resolve. "Engulfing" has been given at least three widths: a candle breaking the high of the single previous red candle; one swallowing the previous *three*; one covering the several smaller candles before it. He also gives inside and engulfing candles identical weight, since an inside candle on the 5-minute is an engulfing candle on the 15-minute.

7.4 What makes a candle good enough to act on

The close. He doesn't enter until the candle closes on his trading timeframe, reading all signals and exits on a closing basis, which keeps him in trades through intrabar reversals. A level is broken when a candle closes outside it, not when a wick pokes through. His named failure mode is entering with two minutes left in a big green candle and watching the body turn into a wick and close red; he enters on an open candle only with ten to thirty seconds left.

Body-to-wick ratio. Entry is always off a big green candle for a buy or a big red one for a sell, a hard filter. He rejects setups where every candle carried an upper wick, and skipped a green retest candle purely for a wick on top. By 2026 he's quantified it as a personal **70-30 rule**: about 70% body in the trade direction, wick under 30% and ideally 20-25%. In practice he softens it, accepting some wick if the body is quite big. Direction decides which wick disqualifies — for a buy it's the upper wick that spoils the candle.

Size. The entry candle must be large and larger than the opposing candle before it. Tiny confirmations are rejected as dojis — roughly 0.4% is not a candle at all, with a minimum "above 1%". There's a ceiling too: he skips the trade if the candle is *too* big, and won't buy into a huge breakout candle, waiting for price to come back to his level.

One candle or two. From 2023 the default is two, entry on the second, with at least one clean and wickless. The exception is precise: if the entry

candle is bigger than the previous ten you can take a single candle, otherwise wait.

Editor's note — what a 70% body filters, and what it does not The 70-30 rule is the only quantified candle-quality criterion in the corpus. What it cannot tell you is *size*: a 70%-body candle on a quiet bar and one during a major announcement are the same shape and completely different events — why he bolts on a floor of about 1% and a ceiling per instrument.

7.5 The chart patterns he keeps

A chart pattern is a combination of candlestick patterns, candles read in groups rather than singly.

Double top and double bottom are the constants — the most basic patterns and the ones he actually uses, M and W, the same thing in opposite directions. A double top is price rejected from the same resistance a second time; a double bottom is the market taking support, returning to it and rising again. Touch count grades it: two make a double top, a triple is better. The *breakout direction decides the name* — the same structure is a double top if the break is down and a double bottom if up, so wait for the price action rather than pre-judge.

Head and shoulders and its inverse are the second constant: an extended double top, sold when the neckline breaks — the market can't break the level, then breaks it but can't hold it, then can't break it again. Never expect a perfect one: real ones are lopsided, and the only constant is the right shoulder staying below the head. He generalises: chart patterns never appear as drawn in books, so use the theory rather than expect the picture.

Triangles. Ascending is roughly equal highs against resistance with higher lows; descending is lower highs over flat support; symmetrical is neutral consolidation between two trendlines. Enter only on the breakout, never earlier inside the pattern however good it looks.

Flags and consolidation are the continuation family, with deflationary vocabulary — "flag" simply means consolidation. A bullish flag is a strong upward breakout then a consolidation drifting back at an angle, the bear flag its mirror. He rates the flag very important, because market movement is always breakout, consolidation, breakout — the most important thing to study.

Consolidation quality is where this earns its keep. A level that breaks immediately with no time spent at it mostly fails; one that breaks after price has consolidated below it mostly succeeds, and longer consolidation gives better probability. He also keeps the **box** — support and resistance at the same places repeatedly, hit several times before it counts. Two smaller shapes recur: the ****V pattern****, his favourite, a fast recovery entered when the bulls win with a breakout — the breakout is the trigger, not the V; and the **N pattern**, price running up, sent back down, then up

again from there, which he later requires (or a consolidation breakout) before any breakout trade.

What he throws out is as informative: rounded tops and bottoms as boring and rarely working, the staircase as only confirming the trend is holding, XABCD and harmonics as useless, and the long tail of fanciful named patterns outright. On chart *types*, nothing beats candlesticks and Heikin Ashi, Renko, Kagi and point-and-figure are disturbance.

His actual traded set is where the statements disagree. In 2023 he restricts himself to two strategies, price action or retest, telling viewers not to trade ascending triangles or flag and pole. In 2024 he trades three — breakout after consolidation, retest, and double top or bottom — dropping head and shoulders and triangles, because a fourth pattern makes the win rate worse. In 2026 he teaches exactly four: double top and bottom, head and shoulders, traps, triangles. Within triangles the position reverses outright: in 2025 ascending and descending consolidations are valid; in 2026 he trades only the symmetrical, refusing the others for giving too many fake breakouts. He doesn't acknowledge the reversal. What survives every version is the core pair, which he calls the easiest chart patterns in the market, with the instruction to master two or three and backtest those few over two to three years.

7.6 The neckline: the one rule that governs the entries

He never trades the pattern itself; he trades the break of the minor level inside it. The neckline is nothing more than a minor support, the small support between the two tops, or any minor level whose breakdown is the signal. The rule is absolute: never enter right at the top of a double top, wait for the neckline to break, since entering at the extreme is too weak a setup to succeed long term. He will not take the double bottom itself either. For head and shoulders he shorts only at the neckline, whether the market retests it and drops or falls through directly.

The stated reason is a failure rate: back-test double bottoms seriously and you'll be shocked how often they fail. Most double bottoms on small timeframes are bad ones — "bad" meaning the neckline never breaks — and the public loses by buying them in a hurry. Buying the second bottom is the gambler's trade.

Three refinements sit on top. The confirming candle: a double top is sold when the neckline breaks with a red power candle. Structural filters: only double bottoms whose second bottom consolidated sideways before recovering, with a V-shape recovery before the breakout. And a tolerance at the touch but not at the break: at the second bottom a wick touch is accepted and the body doesn't matter, while what must actually break is the neckline.

Stop and target hang off the same level. On a double-top short the stop goes a little above the neckline, since a genuine breakdown shouldn't trade

back above it, making the level the invalidation point rather than an arbitrary distance. The target is the starting point of the developing pattern, checked before the trade for how far it can extend after the break, as the test of whether risk-reward is acceptable.

Editor's note — why the neckline rule is the testable part of pattern trading "A double bottom formed" is not a testable event, since whether two lows count as one pattern depends on tolerances a human eye supplies; "the market closed above a specified price" is. By moving the entry from the shape to the neckline he converts a subjective pattern into a conditional order with a defined trigger — the single most transferable idea in this chapter.

7.7 Where the pattern is read: patterns across timeframes

Chart patterns sit on the middle timeframe, candlesticks on the lowest. One timeframe below the level-drawing chart he looks for trend and chart patterns, and on the lowest for candlestick patterns and the breakout, where the entry is taken. On a 4-hour chart he refuses to read patterns, trend or structure at all, doing that on the 1-hour — the reason is horizon: a pole-and-flag target on a 4-hour chart took six days to hit, so the pattern is irrelevant if you intend to exit within a day or two.

Agreement across timeframes is quality, defined loosely on purpose: he wants the same pattern on both, but "same" isn't identical — a double top on one and a head and shoulders on the other is acceptable as long as they point the same way. Where timeframes disagree the bigger wins, and he declines to short a double top and neckline break against the higher-timeframe trend. The exception is intraday, where trend bias is suspended entirely — a breaking double-top neckline is a short even inside a larger uptrend. As in [[Ch. 6]], the two positions are reconciled only by horizon, never explicitly.

7.8 How much he thinks a pattern is worth

He's more sceptical than the teaching videos alone suggest: no pattern works permanently, the market changes, so don't be dependent on one. On the obvious version — sell when support breaks, buy when resistance breaks, trade a head and shoulders — he says it works about 2-3 times out of 10, then restates it minutes later as 3-4 out of 10: one loose claim spoken twice, meaning roughly a third of the time. By 2025 classical patterns don't work by themselves and need something added, unspecified beyond confirmations and market understanding.

There are instrument and regime restrictions. Breakout patterns work well specifically in the stock market, and he pointedly declines to claim the same for Nifty, gold or Bitcoin. In 2026 he says double-top and other reversal concepts are useless in forex and crypto, since the pattern exists

on one broker's chart and not another's — against his 2024 claim that the double top works in forex as well as the Indian market and his own run of forex, gold and crypto trades on those patterns. It's later and has a mechanism, so it reads as a genuine revision, but he never retracts the earlier teaching.

He's candid about his own failures: an AUD/JPY short with a downtrend, lower high and big engulfing candle breaking support that lost anyway, kept as a correct setup with a bad outcome; a clean inverted head and shoulders breakout that still forced a loss.

One conditional split looks like a contradiction and is not. Once *in* a trade he refuses to act on opposing patterns: only target, trailing or stop loss exist after entry, a single candle being insufficient information to manage a trade on. Against that, he's cut a long at a loss and reversed when a perfect double top formed against him — immediately calling it a special situation not to be repeated. Read together: a completed opposite *chart pattern with its neckline broken *can override an open trade, a single opposing candle** cannot.

What he doesn't say about this

- **How often any pattern actually works.** The only figures are loose and

self-labelled as such — the textbook signal at 2-3 or 3-4 times out of 10 and the N pattern at 50, 60 or 70 percent. No backtest, sample size or hit rate appears anywhere.

- **A measured definition of "engulfing."** It means the previous one candle in some

videos and the previous three or several in others, and he equates the inside candle with it on a timeframe argument. He never settles it — the likeliest place for a reader to implement something other than what he trades.

- **Volume as a pattern filter.** Volume appears only in passing; the classical

requirement that a breakout be confirmed by expanding volume is absent.

- **Whether reversal patterns work outside equities.** His 2026 statement that they're

useless in forex and crypto contradicts his 2024 statement that the double top works in both and his own record of trades there.

- **Targets from the pattern's own geometry.** The classical measured moves aren't part

of his method; his targets are the pattern's starting point, a fixed 1:2, or a check on how far the target *can* extend.

Chapter summary

- Patterns are the last input, not the first: only actionable at an area of interest,

and placement matters more than shape, size or colour.

- One principle covers all candles — the wick shows where price does not want to go, the

body shows which side had control — and a candle with wicks on both sides gives no signal.

- He reduces the candlestick zoo to three types — power (engulfing), rejection

(hammer/pin bar) and doji — renames the first two, and tells students to learn no others.

- The doji is never an entry: it's a hint, tradable only through the candle that follows

it.

- A candle qualifies as a trigger on the close, with about 70% body and wick under 30%,

and normally two candles unless one is bigger than the previous ten.

- His kept chart patterns across every version are double top/bottom and head and

shoulders, plus triangles, flags and traps depending on the video; he discards rounded tops, staircases, harmonics and fancier named patterns.

- The entry is never the pattern, it's the neckline break — the minor level inside the

pattern — with the stop just the other side of it.

- Chart patterns are read one timeframe below the level-drawing chart and candlesticks

on the execution chart, with the bigger timeframe prevailing on conflict — except intraday, where he suspends the trend filter.

- He's openly sceptical of what a pattern is worth: no pattern works permanently, the

obvious textbook signal works roughly a third of the time.

Try this

The two-pattern backtest. Master two or three chart patterns, drop the rest, and backtest those few over two to three years, treating each as a

standalone strategy. Given his neckline rule, the version that matches what he actually trades records two results per pattern: one taking the entry at the second top or bottom, one taking it only on the neckline break — the comparison he says will shock you. For live practice without risk, name the pattern forming and the condition that would trigger the trade — "if the neckline breaks here, then I take a long" — written down in advance across a watchlist, with no position taken.

Chapter 8 — Entry Mechanics

In this chapter: the moment of pressing the button — the fixed order in which he decides an entry, what he accepts as confirmation, the argument he keeps having with himself about entering before a candle closes, the four entry models he permits, the setups he refuses to chase, how he splits an entry into pieces, and the clock rules that decide which hours a trade is allowed to exist at all.

Chapters 5-7 covered the setups and the reading that produces them — analysis. This chapter is the last few seconds, where analysis becomes a filled order, and it's the part he treats as most fixable: on a Nifty fib-retest buy the technicals were correct and the loss came purely from being late.

8.1 Why the entry gets its own chapter

Entry is one of the very few things a trader controls: you can't control the market, only your entry and exit. In his four-part trading plan the first decision is entry criteria, and where he wants the rest of the plan simple, the entry criterion is the one component he insists must be sophisticated.

The reason is mechanical, and almost every rule below reduces to it:

****entry location sets stop size.**** A badly-timed entry leaves the stop far

too large — he already knows he wants to be in the trade, and the timing decision is purely about how much room he has to give it. He drops to a 15-minute chart after a 1-hour gold breakout specifically to keep the stop small. Buying at the extended point of a move is the worst position; the right positions are the pullback levels inside the trend.

Editor's note — why this is a constraint, not a preference If the stop must sit at the price that invalidates the idea, moving the entry further from that price widens the stop; and since risk-per-trade is capped in currency terms ([Ch. 11]), a wider stop means fewer units and less profit from the same move. Entering twice as far from the invalidation point roughly halves the position for identical risk.

8.2 The order of operations

One sequence runs through the whole corpus: bias, meaning whether to buy or sell; then important levels; then confirmation, read off the candlestick, last. The higher-to-lower timeframe drop is its physical form — open the 4-hour for structure, the 1-hour for trend, enter on the 15-minute. The four-hour chart is for zones only, never the entry.

The sequence forbids entering because you happen to be looking at the chart. He never enters on a random candle and always waits for price to reach an important level first. The strategy reduces to two steps: find an area of interest, then wait for a reaction there — both required, arrival

alone isn't enough. Levels are marked in advance and the trade taken only when the alert rings; buying blind at a low is guesswork. He equally refuses the reverse ordering — trading first and finding a reason afterwards. Trading without a signal is turning up at a wedding without an invitation card: mechanically, if A then B, if B then C, and only if C happens do you enter.

He also insists on stacking: trading is never done off one thing, three or four things have to coincide.

8.3 What counts as a confirmation candle

The most repeated instruction in this material is that the entry is taken off a candle: entry only on a big green candle for a buy or a big red candle for a sell; until the signal candle appears there's no reason to sell and none to buy.

Two candle families are permitted. The power candle: a large green body with small wicks, the first acceptable reaction at a level. And the rejection candle — a lower tail with a green body, which he calls a hammer. These are the only two, everything else ignored. Which one depends on the job: the power candle is always for breakouts, the pin bar always for reversals.

The exclusions are as specific as the inclusions. He rejects "boring candles" — dojis and candles whose wick and body show neither rejection nor power; the doji is never a confirmation candle, it only hints a reversal may have come. On a forex 15-minute example he puts a floor of 10-15 pips on a "solid" breakout candle while rejecting one of 7 pips — the one place he quantifies the word. **By 2025-26 he has put a number on it generally:** the 70-30 rule — about 70% body in the trade direction with the wick under 30%, ideally 20-25%. In the New York session strategy it's a hard filter, or the entry is discarded.

Location gates the candle, always. A bullish engulfing candle is a buy candle but must not be bought everywhere it appears — the patterns are only a buy at an important level; the same red candle at an unimportant level means nothing. He grades candles subjectively — a bullish engulfing after a proper downfall scores 9 out of 10, a quality grade and not a win rate.

8.4 The close, and the argument he keeps having with himself

A level is broken when a candle closes beyond it, not when price touches it; he wants the body to close beyond and ignores repeated pokes that don't. The minimum timeframe he takes closes on is 15 minutes: an entry that reaches the level without a 15-minute close doesn't activate.

Then there's the open-candle question, the most honest running argument in the corpus. His doctrine: he doesn't enter until the candle closes on the timeframe he's trading. Entering on a candle that hasn't yet closed is mistake number one, and a loss taken without confirmation is a bad loss even when the setup was good. Entering on an open candle is only for traders with a lot of experience — as a beginner, do not.

And then he does it anyway, and says so. He enters on an open candle himself, but only with ten to thirty seconds left, never with three minutes left — the same "20-second rule" he gave three years earlier: if the stock hasn't made the move during almost the whole candle, it won't make it in the last 20 seconds. He also names the cost of always waiting: the market sometimes never gives a chance for a closing confirmation, so if the candle turns out big you either couldn't have entered at all or would've had to give too big a stop. The early entry gets its own invalidation: if the candle closes back above the level he cuts immediately. Treat the close as the rule and the open-candle entry as a discretionary override he claims for himself and withholds from beginners.

8.5 Four entry models, and the timing rule attached to each

Broadly two entry models, he says: breakout is price hitting a level repeatedly and then bursting through; reversal is price hitting once and falling straight back. His 2023 magnet-level strategy permits three: trap, reversal, and breakout-and-retest. Each carries a different timing

instruction, and the differences are where most apparent contradictions live.

Breakout. He's never taught taking direct breakouts: never buy directly even at the cost of missing the opportunity, with a retest entry allowed instead, because buying a breakout the first time mostly doesn't give results. His own rule is price touching the level, taking a small pullback, then breaking it — that break is the buy. He calls the shape an N-pattern: a plain breakout on a small timeframe is low quality, an N-shape breakout is what he wants.

Retest. Retests are the best entries and he always tries to trade the retest rather than the breakout. He splits entries into a risk entry on the break and a retest entry after the pullback, calling the retest the perfect entry while still taking risk entries himself. He's honest about the cost — a lot of the time there's no retest and the stock launches directly — and accepts it by asymmetry: if the market never pulls back you make no loss, and if it does you can make a big profit. It's binary — a green candle at the retest is the pass, he won't buy a red candle there.

Reversal. Never short the reversal itself, on the first touch of the point of interest; never trade the first touch of a level, never the first breakout — the first fall from a level cannot be traded because nobody knew in advance it would fall there, and taking it is what a gambler does. He defines reversal narrowly to enforce this: price touching support and running away isn't a reversal — a reversal means price takes support, rises, comes back down, and forms a structure such as a double bottom

before he buys. So he won't buy the second bottom of a double bottom and waits for the neckline to break.

Trap. The trap is where "never the first" reverses: in trap trading you sell on the first one, the direct opposite of his reversal rule. A trap is price breaking out of a level and then closing back inside it — the close back inside makes it a trap, the break alone doesn't. He shorts the moment price closes back inside after breaking out above, without waiting for the neckline. Come in directly — there's not that much time.

Editor's note — the four models are one rule seen from four angles

The timing instructions look contradictory in isolation but are consistent: in each case he waits for the market to demonstrate that the level has already defeated an attempt. The retest is the breakout proving itself, the second touch is the reversal proving itself, and the close back inside is the breakout *failing*, itself a demonstration — so the trap needs no second attempt. The reconciliation is editorial; he never puts it in these terms.

8.6 What he refuses to chase

A large fraction of his entry teaching is about trades not taken, governed by his oldest statement: buy low, sell high, where resistance always counts as the high. He won't buy into a move that has already run — buying after the momentum move has happened is a mistake, because the market

moves in patterns rather than continuing straight. Buying after the whole market has run up is foolishness, because price comes back and takes out those buyers' stops. The mirror applies to shorts — he refuses to sell into an important support level, wanting to sell at the top and buy at the bottom. Nobody sells at the first high — only gamblers do; he sells at an equal high or a lower high.

When the move is missed, it stays missed. We never chase a missed train; he waits for price to come back slightly below instead, and skips a stock when the breakout has run away — the train has left the station. He accepts the cost publicly: nobody is a superman who can catch his perfect entry. Two fallbacks exist: the retest — he waits for price to come back to the level and buys on momentum, for the smaller stop; and size — if you're late to an entry, put in half your quantity.

8.7 Entering in pieces

He almost never puts the full position on at once — he always enters step by step, calling it a step entry. The reason is timing rather than risk arithmetic: taking full size immediately has made him late to the trade.

He enters a partial size first and adds only when the market gives confirmation — probing means entering small, adding only if the trade goes your way, otherwise leaving it and accepting the loss. Any addition waits until the position has proved itself by moving, rather than being added into a drawdown. He grades the adds: A-quality is a proper pin bar

without the stop being hit, or a green candle; A-plus once a new high has been made.

Size also tracks entry quality on re-entries. After booking a winner he requires a better price or a better reason before re-entering. Re-entry after a stop-out is permitted with conditions: a stop should be there and it shouldn't be a big one. One video runs directly against the doctrine: he places one single entry, thought through very carefully, not a series of attempts at the level — never reconciled with the scaling practice.

8.8 The clock, part one: the Indian session

Time of day is an entry filter with the same status as a level. You don't get to trade simply because you happen to be free. His first psychology rule is to set your trading time.

For the Indian equity session — 9:00 to 3:30, intraday meaning starting by 9:30 and cutting by 3pm whether in profit or loss — the recurring instruction is to skip the open. The oldest version is a hard 10:45 rule: start at 10:45, not the 9:15 open, to avoid the fake signals that cause early-morning losses. The clock time itself isn't the point — the rule is about ignoring the early-morning reversal window, and 11:00 or 11:15 would serve equally. Later versions cluster around 10:00-10:30 — watch the first 15 minutes rather than trade them, come to the market around 10:00-10:30

and leave if nothing is there. A 2026 version generalises away from the clock: do nothing for the first 30 minutes and let the market build a range.

The other end of the day is gated too — no intraday trading between 2:30 and 3:00, since that window belongs to the next day's swing or BTST trade.

Not everything is time-gated. Swing entries have no fixed time of day. And a first-15-minutes range strategy puts the entry deliberately early — whenever the opening range actually breaks. That's how the same instrument can require a 10:45 filter in one strategy and permit a 9:35 entry in another: the second trades the opening volatility rather than trying to survive it.

8.9 The clock, part two: 24-hour markets

Timing matters in forex specifically because the market is open 24 hours, which leaves traders confused about when to trade. His answer is to impose an artificial session on yourself: fix your own window of two to four hours. The session map is in Indian time, a deliberate channel convention. London runs roughly noon to 6-7pm IST, New York 6pm to midnight.

The window he recommends is the volume window — the London-New York overlap, roughly 4-8pm IST, is the highest-volume time of day.

Several published strategies encode the window as a hard rule: the magnet-level strategy takes trades only between noon and 9pm India time, so you don't have to stay up all night for a 24-hour market. He passes on valid setups outside the window, saying to stop at 10pm and sleep even though the session is open — for the sake of your life rather than anything about market structure.

8.10 Testing the clock instead of asserting it

One 2024 video is the only place he derives timing rules from data rather than stating them. Working from a strategy sheet, he runs a time-of-entry filter first — isolate all trades taken at one entry time and count targets versus stop-losses for that time alone. Once a time filter shows improvement, he layers a day-of-week filter on the surviving subset, not the whole sheet.

The numbers are specific to individual strategies and he says so repeatedly. For one Bank Nifty strategy the 9:15 entry produced 10 targets against 25 stop-losses — a very bad time for that strategy, while other strategies work at 9:15. Within the surviving filter, Wednesday gave ten targets against four, a 71.66% win rate; he stops trading that strategy on Mondays and Fridays, stressing that another strategy may have different good days. In a gold strategy the 12:30 entry candle produced one target against twelve stop-losses and he's removed that time from his career entirely.

Set against this, he's candid that published timings are usually asserted rather than derived: asked about the 10:00am and 11:45am rules in one gold strategy, he says the timings were planned deliberately but declines to explain the theory. The hazard he never raises is multiple comparisons: twenty entry times crossed with five weekdays offers a hundred cells, and the best-looking cell will look impressive by chance alone — ten targets against four is fourteen trades.

What he doesn't say about this

- **He never fixes the boundary of the open-candle exception.** The rule is to wait for

the close; the exception is a ten-to-thirty-second window, stated inconsistently and without naming the candle timeframe it applies to.

- **"Big candle" is defined once and estimated everywhere else** — a floor of 10-15

pips on a forex 15-minute candle, a 70-30 body ratio on later strategies; elsewhere "clear, definitive," "solid" and "power" are left as visual judgements.

- **He gives no expectancy for the confirmation trade-off** — waiting costs entry price

and missed moves, and he asserts the confirmed version is better, but the only place he supplies numbers is the time-of-day backtest, not the confirmation question.

- **Session times are given in Indian clock time and rarely converted**
— a deliberate

channel convention, but most of the timing rules here are unusable without it.

- **He does not address slippage, spread, or order type in most entry rules** — the

exceptions are narrow.

Chapter summary

- The order never changes: bias first, then the level, then confirmation read off the

candle. Higher timeframe decides direction, lower timeframe places the entry.

- Entry location is a stop-size decision: a badly-timed entry makes the stop too large.
- Only two candles are permitted — a power candle for breakouts and a wick-rejection

candle for reversals — and both only at an important level. The later quantified form is a 70-30 body-to-wick ratio.

- A level is broken on a close beyond it, never a wick. Entering

before the close is his stated mistake number one, permitted to himself only in the last ten to thirty seconds and withheld from beginners.

- Never the first: not the first breakout, not the first touch, not the first reversal,

not the second bottom of a double bottom — with the trap as the single stated exception, taken on the first occurrence.

- Missed is missed: he does not chase. The two permitted recoveries are a retest entry

and half size if late.

- He enters step by step and adds only after the position has proved itself; re-entry requires a better price or a better reason.
- Time of day is a filter with the same standing as a level: skip the Indian open and

start around 10:00-10:45, and in 24-hour markets fix a two-to-four-hour window of your own, preferably around the London-New York overlap.

Try this

Run his time-of-entry filter on your own record. Isolate every trade taken at one entry time and count targets against stop-losses for that time alone, then — and only then — layer a day-of-week count on the surviving subset rather than the whole sheet. Before acting on the best-looking cell, note how many trades are in it — his own strongest weekday result rests on fourteen.

Chapter 9 — Stops and Targets

In this chapter: where the stop goes at the moment of entry and why, the reference points he actually uses, the rule he repeats more than almost any other — never be stingy with the stop loss — the difference between the stop-loss *order* and the *invalidation level* it stands in for, how the target is chosen from the chart before the ratio is checked, and the trades whose geometry disqualifies them before they're taken.

This chapter covers the decisions made in the last seconds before the order goes in. What happens once the trade has moved — breakeven shift, partial booking, trailing, pyramiding — is [[Ch. 10]]. Almost every tightening rule he teaches is conditional on the market having already paid, and none of it is done from entry.

9.1 Why the stop is the first thing decided

His mechanical definition: an instruction to the broker to cut the trade at a set price so the loss goes no further. The definition that carries the chapter is the other one: the stop loss is the point at which, if price reaches it, he is wrong — a precondition for entering at all, which is why he calls the stop

the best risk-management tool there is. It's one of four pre-trade decisions — entry criteria, stop loss, quantity, exit target — and with those four settled the plan is made.

What the stop buys is knowledge rather than protection: it tells you in advance how much calculated loss is going to happen, which is what lets him stay calm. Trading without one is the first reason accounts are lost and will finish a career before it starts.

He has broken the rule in public. Through 2025 he ran a positional Bitcoin position with no stop at all, planning to hold through a 30% crash, while stressing his intraday and swing trades all carried stops. He attributes a whole blow-up to it and commits to never doing no-stop-loss trading on leverage again, with one exception — averaging into investing assets.

9.2 Logical, not affordable: the stop is a chart fact

The most consistently repeated structural claim in this material is that stop distance isn't chosen by the trader — it's read off the chart, and position size adapts to it. To a questioner complaining of repeated stop-outs: the stop must be logical rather than tight, and if the logical stop comes out bigger, reduce quantity rather than tighten the stop. The stop isn't there to cap your loss at a chosen rupee amount for the day. When a valid setup carries a wider stop he names exactly two options — don't trade, or reduce

quantity — never moving the stop closer to fit the size. In forex it's an identity: lot size is the variable, not the risk.

Two tests for "genuine": it sits on a support or resistance level rather than a distance you picked; and if the stop needed under a support would cost more than the allowed percentage of capital, he disqualifies the trade rather than shrinking the stop.

The sizing step is always the same shape: divide the amount you're willing to lose by the stop-loss distance to get the lot size. The inverse holds and he uses it aggressively — he increases quantity when the stop is unusually small, because risk per trade is unchanged at double or triple the size, taking thirty lots in one index because the stop was a single candle wide. His argument against tightening artificially is behavioural: an artificially tight stop gets hit, and then the target hits anyway, leaving a useless loss instead of the profit.

Editor's note — the identity he is working from Every sizing statement above is the same equation: $\text{money at risk} = \text{stop distance} \times \text{position size}$. Fix the money, let the chart supply the distance, and size is the only unknown. This is fixed-fractional position sizing; what he adds is the ordering, chart first and arithmetic second. He doesn't address its known cost: size becomes very large when the stop is very tight.

9.3 Where the stop actually goes

Asked for a "logical" stop, he gives a list rather than a rule: below a pivot, below a moving average, below a level, or at the day's low or high — whichever is nearest.

The entry candle is the default for a fresh entry — below it for a long, above it for a short. One candle or two is decided by candle size — below one if the candles are big, below two if small. **Half a candle** — where a full-candle stop would be too wide, place it at 50% of that candle, with the fallback that if even the half-stop is too big, you still put it a little below and not stingily. **Structure and levels** — beyond the candle, the reference is whatever structure the trade came from: the swing high or low that formed the setup, the level broken out of, a moving average, VWAP a rupee or two beyond rather than exactly at it. For zones the stop goes beyond the zone; for pattern trades, the pattern's own invalidation — below the neckline on a head and shoulders, notably a little *above* the neckline on a double-top short rather than above the pattern high.

Wick or body. He isn't consistent. On a gold long he places the stop beneath the wick rather than at the body, because the market can defy the wick. In options he does the opposite deliberately, leaving a small space from the body rather than the full wick, to keep premium risk limited.

F9.1 — his stop-placement logic, reconstructed from the sequence of preferences he states: structure first, candle size as the fallback, and the ratio check as the final gate. This is a schematic, not a claim that he checks it in this exact order himself.

F9.1 — his stop-placement logic, reconstructed from the sequence of preferences he states: a nearby structural level first, the entry candle's size as the fallback, and a final risk-reward check that can still veto the trade. This is a schematic, not a claim that he checks it in this exact order himself.

9.4 "Never be stingy with the stop loss"

The stop goes a little *beyond* the level that justifies it, not exactly on it — repeated in near-identical words from 2021 to 2026: never stick the stop flush against the candle; never be stingy. Buffer sizes are instrument-specific examples, not rules: about ten cents on gold, about two rupees below the day's low on an Indian stock, three pips beyond the level in forex to absorb the bid-ask spread.

The paired instruction gives the chapter its shape: you may be miserly with the target but never with the stop loss. He names deliberately tight stops at entry as one of his three "money mistakes," and puts tightening only after the trade has moved in your favour. A stop just above the swing point, where everybody expects it, will always get hit because of volatility. Three reasons: a trade needs breathing space at the start; the first adverse candle removes weak hands before the market goes where you thought; and a roomy stop is what lets a high-win-rate strategy work at all, because a tight stop takes you out on the pullback.

The rule has a stated ceiling: if the required stop is unsafe, the trade is missed. A big stop loss on a small account is mistake number one. In one 2026 live session he tells viewers not to be stingy and then halves the stop on the running trade minutes later.

Editor's note — the buffer is a liquidity argument, not a superstition His reason is behavioural: a stop where everybody expects it will always get hit. The mechanism he supplies elsewhere without connecting it — a short seller's stop is a buy order, so obvious levels accumulate resting orders and his own stops "become liquidity." A few ticks outside the crowd doesn't exempt you from that, but it keeps you out of the first wave.

9.5 Touch or close: what counts as being wrong

The beginner rule is a touch: always a stop loss and always on a touch basis, with closing basis reserved for experienced traders who can read the other factors. The closing-basis version is mapped to holding period, not preference: 15-minute closes for an intraday trader, one hour for short-term swing, daily for regular swing — the level stays the same and only the closing timeframe changes.

The exceptions are firm. Closing-basis stops won't work in Bank Nifty option buying, where they can produce a huge loss, since sometimes the

wick doesn't come back. In forex he requires the stop to be in the system rather than held mentally or on a closing basis, because one big candle can take back months of profit — and practically, a system stop simply gets hit, so waiting for a close is only available to someone not putting the stop in the system at all, which invites extra risk for a very small chance of the bounce.

9.6 Where the stop lives: the system, or the hand

The default instruction is unambiguous and repeated for years: an actual order in the system, not a mental one. The reason is availability: a hand-managed stop leaves you dependent on where you happen to be. He credits it with a save on an event-driven gold move that would otherwise have cost thousands of dollars and blown the account.

Against that stands an unresolved counter-practice. In options he doesn't put the stop on the system and cuts by hand when the level is touched; in a 2026 live session he says the stop always has to be cut by hand, acknowledging resting-order methods exist but saying they often get stop-loss hunted. In January 2026 he says he either keeps the position fully open to close by hand, or works with the stop in the system — visible tension with the blanket instruction he'd given moments earlier. The instruction to viewers never softens; his own practice does.

In options specifically he refuses to derive the stop from the premium chart: he analyses the index and looks at the option chart only to place the stop and target, because ITM, ATM and OTM premiums behave differently and decay moves the number through the day. And the price you're watching may not be the price your stop lives on: the chart in TradingView may not be the feed your broker uses, so a stop can hit on the broker's chart without hitting on yours — the difference runs roughly two pips in forex from different liquidity providers, or up to a hundred points on the same index between two platforms. The operational rule follows: set the stop from the number shown on the platform the order actually executes on.

9.7 Invalidation is not the same thing as the stop-loss order

The sharpest distinction in the chapter is one he draws in practice more often than words: the price at which the idea is dead is not necessarily the price at which the order sits.

The clearest demonstration is a 2021 hedged index trade with two exit layers: the trade's *invalidation* is a closing above the all-time high on the index chart, while a hard SLM order runs on the option premium, priced off his 2% rule. The index level is the discretionary trigger; the premium order is the money backstop. Stated generally: the invalidation is a technical level marked in advance, a closing beyond it — not a retest or confirmation candle.

Because invalidation is about the idea and not the money, it fires where no stop-loss order is involved. If the level doesn't break as expected, he cuts at no profit and no loss rather than waiting for the stop; a trade that goes his way first and then turns back is cut at breakeven, one that goes straight against him is left to the stop. Setup-quality rules void a trade before entry entirely: if the market moves ten points against a Dow breakout, the breakout has failed and the trade isn't taken at all — a filter on entry, not a stop rule.

Editor's note — why separating the two is worth the trouble He never names the distinction but runs it constantly: the invalidation asks "is the idea still true?", the stop-loss order asks "how much am I willing to pay to find out?" When the second is tighter, the trade can be closed while the thesis is intact — a sizing problem, not an analysis one. Both must be written down before entry, or the tighter is discovered emotionally, in the moment.

9.8 The target: the level first, the ratio second

Stops and targets must both sit on some logic rather than being arbitrary numbers. His reason for not picking a number: nobody knows how far the market will go, so the target has to come from a technical tool, not a guess. The method he settles on: the risk-reward-ratio method alone isn't

the best way — the best is the ratio method combined with the logical method. The order is stop first, placed logically; then target at the next resistance identified on the chart, not derived from a ratio; then a check that the resulting ratio is acceptable before the trade is taken. The substantive point is stable across his (occasionally reordered) statements of it: the ratio is an *output* of the levels, not an input.

The target references mirror the stop references — the next marked level in the direction of the trade. For bigger targets he goes up a timeframe and marks the level there: the higher the timeframe, the bigger the target you can take. Where no level exists, the fallback order is explicit: the next overhead levels, then the 200 EMA, then monthly pivots, and only if all three fail, a plain 1:1.5 or 1:2.

Two constraints act as filters. The target is capped by the level, not by the ratio you'd like — it must be counted only up to where support sits, so a trade offering only 1:1.3 to that support isn't a good trade. The second is available room: he rejects an otherwise valid triangle breakout because only about 4% of room remained to the previous high — a race analogy where the runner with the least distance left wins even if most tired, so the first check on any breakout is how far the market has already run.

9.9 The ratio floors, and who they change for

The spine is 1:2, stated as early as 2020 and as recently as 2026, where at least 1:2 is non-negotiable. The floor beneath it is 1:1.5 — the minimum, with 1:2 the aim; not below 1.5, because the habit and the quality get spoiled. On his own capital, aiming for 1:3 or 1:4.

The floors move for stated reasons. **Direction relative to the trend:** a counter-trend forex trade floors at 1:1.5, with-trend trades go to 2, 2.5 or 3. **Whose capital it is:** on funded accounts, target 1:1 or 1:1.5, explicitly not 1:2 or 1:3 — take the 1:1 and get out even when more is available; on your own capital, the same setup goes to 1:2 or 1.5 ([Ch. 12] covers why). **Instrument:** stop and target bands shift by market — tighter in equity intraday, wider in forex and crude — but the ratio floor doesn't move with them. **Options premium:** a genuine stop for an option buyer is at least 30% of the premium — what the option's own volatility requires, not a chosen risk level.

9.10 Stingy with the target

The counterpart of never being stingy with the stop is being deliberately stingy with the target: exit at the level like a miser. Operationally, he books just short of the obvious price — about half a per cent short of the popular level, just before round-number levels rather than at them. The reason is crowding: the level is visible to everyone, so the market reverses

there while you're still trying to book. The rule isn't uncontested in his own mind — quoting a teacher that no one becomes poorer by booking profits, he agrees, and then says his own psychology holds that booking small profits makes you miss big targets, citing a silver move that got away. Both behaviours appear — the shaved target dominating his teaching, the held target his own trading.

One asymmetry is decided at entry: the stop goes into the system and the target frequently does not. In crypto the stop must always be placed and the target never — keeping the target open and the stop closed, because crypto sometimes gives a move bigger than you can imagine.

9.11 The trade you do not take

Because the stop is a chart fact and the target is a level, the two can simply fail to make a trade, and he treats that as a normal outcome — a stop that would cost more than the allowed percentage of capital is disqualified. In November 2025 the refusal is at its cleanest: he will not use a wider stop to survive such trades, because then the risk-reward wouldn't work out.

Before abandoning, he has a fixed set of moves — all of which change the entry, not the stop. **Re-time the entry**, the most common: he declines a fresh breakout because the stop would be too big from there, and waits for a pullback. **Drop a timeframe**: when the stop is too wide he goes one lower for a tighter one before abandoning. **Move the target instead of**

the stop: if widening the stop for safety breaks the ratio, he brings the target closer rather than tightening the stop, so 1:1.5 still holds.

9.12 Taking it

Placement is only half the rule; the other half is that a placed stop is honoured. Until the stop is hit, you don't exit no matter what happens. He doesn't touch it once placed, not even at large open loss, never widens and only trails. His memorable formulation: never run and never quit in the middle — take the stop or take the target, or you stay "the monkey in the middle" and get nothing.

Exiting *early* is its own error. The stop was placed under a support in the first place, so the market often bounces exactly where the impatient trader gets out. Asked whether you can tell a trade has failed before the stop is hit, he answers that no one has that answer.

He's candid the honoured stop will sometimes look foolish afterwards — he puts the frequency of "stopped, then target hit anyway" at one or two times out of ten, and separately estimates three or four trades out of ten will hit the stop. He cuts anyway, saying not cutting would only be gambling. He gives the outcome a name: a "good stop loss" is a loss that had to happen according to your strategy, treated as learning rather than error.

What follows a stop-out is capped: two stop losses a day is a mandatory rule he admits keeping only about 80% of the time; the response is

conditional on size — a small stop allows one more try, a big one closes the day. [[Ch. 11]] treats the daily caps as risk architecture; here they're the last clause of the stop-loss rule.

What he doesn't say about this

- **No data on how often each placement method survives.** He never compares candle-

based against level-based stops on the same sample, though he concedes backtested win rates fall live precisely because stops get placed differently.

- **No rule for choosing among his own reference points** when several are available at

once — candle low, swing low, moving average, pivot, zone edge. His "whichever is nearest" is contradicted by his frequent preference for the wider option.

- **No volatility-scaled stop rule.** He rejects both fixed-percentage and fixed-size

stops but offers no substitute measure; ATR appears only as a target check.

- **The system-versus-manual question is genuinely unresolved** — the instruction to

viewers is always the system, his own practice in options and several 2025-26 sessions is to cut by hand, and he acknowledges the split without resolving it.

- **Gap risk is described but not solved** — a technically valid long destroyed

overnight by a gap down, with no method given for sizing around it.

Chapter summary

- The stop loss is defined twice: mechanically, as a resting exit instruction; and

substantively, as the price at which he's wrong, which must be known before entry.

- Stop distance is read off the chart and position size adapts to it, never the reverse —

the two named alternatives when the stop is too wide are don't trade or reduce size.

- Never be stingy with the stop: place it a little beyond the level, because a trade

needs breathing space and the first adverse candle exists to remove weak hands. If the required stop is unsafe, miss the trade.

- Touch basis for beginners, closing basis only for the experienced, matched to holding

period — with options excepted, where a close-based stop can produce a huge loss.

- The stop goes in the system and the target often does not; in options the stop derives

from the index or spot chart, never the premium chart; the level must be read off the platform the order actually executes on.

- Invalidation is a separate object from the stop order — a pre-marked level whose

breach ends the idea, sometimes firing before the stop as a no-profit-no-loss exit.

- The target is the next logical level, checked against the ratio rather than derived

from it, with a fallback ladder of level, 200 EMA, monthly pivot, then a plain 1:1.5-1:2.

- Ratio floors: 1:1.5 minimum, 1:2 standard, 1:3 as a professional stretch, 1:1 on

funded capital — and stingy on the target while never stingy on the stop.

- A placed stop is taken: never widened, never exited early out of fear, and accepted

when the market takes it and then goes to target anyway, which he puts at one or two times in ten.

Try this

Run his stated order of operations on twenty charts. Place the stop first, logically, at the last visible wick or structural level; set the target at the next resistance identified on the chart, not at a ratio; then check whether the resulting ratio is acceptable, rejecting anything under 1:1.5. Do this on twenty historical setups without looking at what happened next, and record how many die at the last step — that count answers a question he never quantifies, how many technically valid setups are disqualified by geometry alone.

Chapter 10 — Active Trade Management

In this chapter: what he does between entry and exit — the short list of actions he permits himself once a position is live, the breakeven shift at the halfway mark that's closest to a signature rule, partial booking and where it helps versus where it quietly destroys the arithmetic, trailing and its costs, pyramiding into a winner, and the discretionary exits he takes before the stop is ever reached.

[[Ch. 9]] covered where the stop and target go at the moment of entry. This chapter begins one second later. Almost everything here is conditional on the trade having already moved: he's emphatic that nothing in this chapter is done from entry.

10.1 Why the post-entry phase gets the most attention

In an early video he lays out a planning acronym where "T" stands for time — the stretch between entry and exit — and puts it at almost 80% of the trading day, naming that stretch trade management. Years later: a trade doesn't end at entry, it begins there. It's also the part inside a trader's control — direction is not, entry and exit are.

What he wants from the phase is asymmetry: always increase the profit while keeping the risk small; manage the downside only, since the upside is the market's to give. Underneath sits the oldest formulation he uses — hold your winners, cut your losers — phrased memorably as being stubborn with winning trades and impatient with losing ones. Holding is the hard half: entries can be handed to you, but holding has to be learned, and it's the single skill he claims to have earned in all his years of trading.

10.2 The short list of permitted actions

His most-repeated structural claim is that the number of permitted actions is very small. In 2022 he puts the whole process at three rules for an open trade: take the stop loss, take the target, or trail the stop loss — anything else is outside the process. In 2023 he calls exiting for any other reason the biggest mistake of all.

Two behaviours are named as the ones to eliminate. The first is **meddling**: cutting when the trade goes slightly green, cutting when a profit suddenly turns red, and shifting the stop loss. A single candle isn't enough information to manage a trade on, and a running trade shouldn't be ruined because of someone's talk, a rumour, or a TV news channel. He names the cost of the alternative: exiting early and then watching the trade hit target damages psychology badly enough that taking the stop loss is preferable to spoiling a good trade.

The second is **watching the P&L**, repeated consistently from 2020 through 2026. Watch the chart instead; the P&L page must be closed completely once a trade is on; repeated checking is an addiction. The reason: whatever green or red you see is unrealised and has nothing to do with the real world, so it only raises your blood pressure.

The mechanical answer is to make the trade not need watching: put stop and target into the system rather than managing manually, attaching both immediately after the fill because attention may go elsewhere; then leave the screen entirely, using price alerts where you need to know. For beginners he prescribes set-and-forget, because a beginner hasn't seen enough to judge developing conditions, and contrasts this with his own active management: his reading of momentum is available to him only because he's traded many times. That boundary recurs throughout.

10.3 Breakeven at the halfway mark

If one rule here is closest to a signature, it's this: once the trade has covered about half the distance to target, the stop moves to entry. He states it in near-identical words across six years — in 2022, once the trade has covered 50% of the planned target he moves the stoploss to around that point or the entry price; in 2023, at 50% of the distance to target he moves the stop to breakeven; in 2024 he calls it his habit; in 2025-26 the trigger is unchanged. Once he adds a frequency claim: at 50% of the way he cuts at breakeven in roughly 90% of cases, hedged with "mostly".

A second trigger is used interchangeably: **target one**. Once target one is reached he reduces the stop loss or moves it to break even. What it buys him is risk removal — a trader's first job. Once the stop is above entry, risk and reward are finished and the trade becomes reward versus reward: small, medium or big. He counts the outcome — his live gold sheet classifies every trade as target, breakeven, trailing or stop-loss and records the percentage of each.

He's unusually honest about the cost. Moving to breakeven at target one still goes negative many times; many times you exit at break-even and the target then hits, and it stings — justified only on the long run. He shows it costing him a trade on camera, taken out at zero on a Nasdaq short before price gave the full target, and says the right response is to do nothing about it, explicitly ruling out widening stops or skipping the breakeven shift as remedies. The residue is self-doubt, because the trader saw profit and gave it back; his answer is that the rule was decided in advance, and doubting a rule you set is what destroys you.

Two refinements. The stop doesn't always go at the exact entry price — on one crude trade he sets the break-even *level* away from the exact break-even price, because price drifted around break even before running to target. And he treats a *reversal* differently from a straight adverse move: a trade that goes his way and then turns back is cut at breakeven, while a stop hit directly is respected.

Exceptions he states. Not on crude oil, which is volatile enough that price comes near the stop, doesn't take it, and then gives the target. Not for option buyers on expiry day, where volatility will simply take the stop out.

And on a funded account with a trailing drawdown rule, never trail — funded traders should instead take half the money off whenever they move to breakeven.

The 2026 self-revision. In June 2026 he turned on his own habit: in his eagerness to move stops to breakeven he's ruined a lot of his own trades, and rushing to cost-to-cost put him on a losing streak even though his analysis was perfect every time. He prefers in that period to absorb a small loss and give the trade space to retest. He doesn't abandon the rule — in the same video he moves that trade to breakeven once it's moved in his favour. The implied but unstated resolution is that the fault is haste, not the breakeven stop itself; that fits the 50% trigger he was still teaching two months later, but it's a reconstruction.

10.4 Partial exits

This is the technique he's least consistent about, and he says so: his booking method changes with the setup, and sometimes he doesn't book at 50% and sometimes he does. The default shape is two targets marked before entry, the first around 1:1.5 and the second around 1:2.

He's most committed to it in **option buying**: half booked at roughly a 50% move or 1:1, a policy adopted after repeatedly watching profits of 40-60% reverse into a full stoploss, because booking half guarantees the trade can't end negative while the rest can still run. The mechanism he cites is decay: booking half early turns an otherwise red option position green when the

trade only reaches breakeven, because theta would leave the P&L red. He scopes it explicitly — not in forex, only in the Indian options market; not in equity.

Against that sits his sharpest objection, scoped to small-timeframe, intraday and scalping traders: booking half is a bad strategy because it wrecks your risk-reward — half at 1:1 and the rest at 1:2 gives 1:1.7 overall while losses are still taken in full. The exception comes in the same breath: partial booking is fine if the strategy stretches to 1:3, 1:4 or 1:5, and swing traders should do it.

Editor's note — checking the 1:1.7 arithmetic He gives the blended figure without working. Half out at +1R contributes 0.5R and half at +2R contributes 1.0R, so the honest blend is 1:1.5. The direction of the argument holds regardless: scaling out truncates the right tail while leaving the left tail intact, lowering expected return in exchange for lower variance.

He revised in the other direction too. In July 2025 he says he's *recently* started booking some lots at target one because too many trades were ending at breakeven, revising the rule given earlier in the same video. As a dated sequence: book-half-in-options (2023) → argue against half-booking for intraday and scalping (mid-2025) → reintroduce partial booking at target one (later 2025) → and by 2026 he tells beginners on funded accounts to remove half the quantity as soon as target one is hit,

since booking part covers the account fee even if the trade gives nothing back afterwards.

He doesn't exit in one click: he scales out with limit orders and lets the remaining quantity book itself at the level, laddering clips at successive rupee levels so the booking happens automatically if momentum comes.

10.5 Trailing

Trailing is gated on two axes: experience and distance travelled.

Experience. Beginners should not trail at all — respect the stop, respect the target, keep it 1:2 until they have experience, add trailing later — because the rush to trail often loses an otherwise winning trade. In 2023 he still tells beginners to remove it from their plan; in 2021 he gates it behind roughly three months of screen time.

Distance. He doesn't trail until 50% of the move or target one is hit; the sequence is breakeven first, trail second. The reason for the delay is mechanical: trailing on every candle close gets you out on the next red candle while the market goes on up. He tells one student that trailing every one or two candles is why he keeps getting stopped out, and that you must respect volatility and not trail "like a miser."

What he trails against. *Structure:* whenever the market forms a support in his favour he shifts the stoploss to it, calling this the thing that produces small losses and big profits — practically, dropping to a 1-minute chart

and trailing under each new higher low. One caveat: you can't trail when there's no pivot nearby to trail toward. *Moving averages*: you can trail with anything, a 9 or 13, usually the 9; for options he gives a tightness spectrum — the 5 EMA to hold very tight, the 9 EMA for some space, the 18 EMA to let the market flow slowly. For longer horizons, the 13 EMA for short-term holders and the 55 EMA for two-to-three-month holds. *Candles and lines*: each time a new green candle closes he trails to just below it; past 50% of target he switches to candle-to-candle trailing on the 1-minute chart.

Two execution rules cut across all three. Everything is read on a **closing** basis — he waits for a good close before shifting the stop up and refuses to exit on a mid-candle indicator colour change. And a trailed stop is never moved back out, because his brain would learn that this is normal and he'd keep sliding it.

The costs, in his own words. He shows a Nifty position where open profit ran to roughly 13-14 lakh, price turned near his target, and the trail cut him out at about half. He counts a doji as a closing and exits on it even where holding paid more — "because rule is rule". The acceptance condition is stated directly: if you want to trail, you must accept that there will be loss. In 2026 he hedges openly, saying trailing has many times got him kicked out of trades so he's trying not to.

Conditions where trailing beats booking: at an all-time high, with no overhead resistance to book against; and in crypto, since a rally can blow away an entire open profit.

10.6 Pyramiding

Pyramiding — adding to a position that's already winning — is the one technique here he treats as an advanced skill with a stated payoff: the same trade pays two or three times more without raising the risk by the same amount, added only after the first position has moved in your favour and price gives another valid entry at the level.

The line against averaging is the point of the technique. Averaging and pyramiding are two different things: pyramiding is to be done, averaging is not. The line is drawn by direction — adding after the position moves in your favour is pyramiding; pouring money in at the same losing point is what people do wrong — and by motive: a person averages out of FOMO and pyramids after seeing price action or a setup. Bluntly: never put more money into a losing trade and always put more money into a winning trade. The difference between the two, he warns, is very thin.

The add is triggered, not taken at will. He waits for a new high before committing more money and won't put in even one more rupee until he gets proof from the market. He grades the trigger: an A add is a proper pin bar without his stop having been hit, or a green candle, becoming A-plus once a new high has been made. He plans the add before entry rather than improvising it, and accepts the compromise: on a pyramid entry you give up getting in as low as possible.

The mandatory stop shift is what makes it safe. When the add doubles his quantity he shifts the stop up so total risk stays where it was, calling it mandatory because doubling quantity doubles risk until the stop is moved.

The arithmetic: 10 lots with a \$10 stop is the same risk as 20 lots with a \$5 stop, and because the added position rides to the same target, a 20-point target becomes roughly 23-25 points of reward while risk stays flat.

Starting small is the precondition. He always enters step by step and never puts the whole position on at once. He credits the probe-then-pyramid structure to Jesse Livermore, defining probing as entering small first, adding only if the trade goes your way, and otherwise leaving it and taking the loss.

His caveats are substantial. He caps it loosely at four pyramid entries and then adds a fifth; one gold trade ran from 10 lots to 40, with risk going up somewhat, just not proportionally. Not every pyramid will work, not every pyramid will hit target, and there won't be a pyramid every day. And the boundary: pyramiding, averaging and occasional extra risk are for your own real account, never a funded one.

Editor's note — pyramiding is a leverage decision wearing a risk-management costume His arithmetic is correct as stated: if the stop moves up by exactly enough, money at risk is unchanged while size grows. What goes unmentioned is *gap risk* — in a gap the loss is size $\times$ the gap, and the pyramided position is several times larger. Read "the same risk" as the same risk *given a fill at the stop*.

10.7 The exits he takes before the stop is reached

The preceding sections describe rules. This one describes the discretion he actually exercises, which is broader than his rules imply.

Invalidation, distinct from the stop. If the level doesn't break as expected he cuts at no profit no loss rather than waiting for the stoploss. He cuts if the market gives a *closing* above the levels he's marked as his new supports — invalidation is a close beyond the level, not a touch of it.

Stalling and time. A position showing no conviction and only consolidating gets its stop tightened rather than waiting for the original one; a stalled trade he's willing to close at no profit and no loss. He has a named fallback he calls back-up trade management: if the trade runs an hour to an hour and a half and then goes sideways, he books the smaller 1:1.5 target instead of waiting for the full one.

Events and the calendar. With a trade already open and in profit when an event approaches, he reduces the stop or trails it to zero; he doesn't do event trading at all, only holding a trade he was already in.

Momentum reads. When an unusually large candle has carried price almost to his target he books into the momentum instead of waiting for the level, because after an unusual burst price typically goes sideways or pulls back rather than continuing to print big candles.

He's candid that some of these exits aren't rule-driven at all: he admits exiting one trade purely because of his mood, cites being psychologically

very tired as part of the reason for closing another, and exits one because he has to leave for a yoga class. He states one as a principle — if you're afraid in a trade you should get out of it — in the same video where he calls the resulting cut a mistake.

The most visible unresolved tension sits here. In one June 2026 video he asks the audience whether to secure most of a large open profit and does so, then seconds later tells viewers never to touch a trade once taken, and states in the same video that whoever wants to earn big money cannot cut the trade in the middle. The honest summary: his stated doctrine is "target, stop, or trail, and nothing else", while his demonstrated practice includes a wide discretionary layer he applies to himself and repeatedly tells beginners not to apply to themselves.

What he doesn't say about this

- **No frequency data on the breakeven rule.** His sheet records the percentage of each

outcome but he never reads those percentages out; the one number he offers is hedged with "mostly." The central rule of this chapter is stated without published evidence of its effect on results.

- **No comparison between trailing methods.** He gives 5, 9, 13, 18 and 55 EMAs,

structural higher lows, candle-to-candle and drawn lines, never compares their outcomes on the same data.

- **No rule for what the 50% trigger is measured against.** "50%" is ambiguous between

half the distance to target and half the observed move.

- **No gap-risk treatment for pyramiding.** The four-entry cap is broken in the same

video, and while risk rose "somewhat" on his largest pyramided trade, he never addresses what happens if the stop can't fill at its level.

- **No instruction on the discretionary layer.** He demonstrates dozens of non-rule

exits while telling beginners to set and forget, without saying when a trader crosses from one to the other beyond a vague "three months" for trailing.

Chapter summary

- The entry-to-exit stretch is almost 80% of the trading day, and a

trade begins rather than ends at entry.

- Once in a trade he permits three actions — take the target, take the stop, or trail

the stop — and treats everything else as outside the process.

- Watching the P&L while a trade is live is banned in every era of his teaching; the fix

is a system stop and target plus price alerts, then leaving the screen.

- The near-signature rule: at roughly 50% of the way to target, or at target one, the

stop moves to breakeven — with the costs stated, that it still goes negative many times and being taken out before the target calls for doing nothing about it.

- He books partials in options and not equity or forex, and argues

against half-booking for intraday and scalping since it blends the risk-reward down while losses stay full size — except where the strategy stretches to 1:3 or beyond.

- Trailing is gated twice: only for experienced traders, and only

after 50% of the move or target one; breakeven first, trail second. A trailed stop is never moved back out.

- Pyramiding means adding only to a winner, with the stop shifted at the moment of the

add so total risk stays flat; he starts small precisely so there's room to add, and warns that not every pyramid works.

- His stated doctrine coexists with a large demonstrated discretionary layer —

invalidation closes, stalls, events, momentum reads, and openly admitted mood-driven exits — which he says beginners should not copy.

Try this

Log the four outcomes. He keeps a live sheet on which every trade is classified as target, breakeven, trailing or stop-loss, with the percentage of each. Reproduce that sheet for twenty trades of your own, applying his stated trigger — at 50% of the way to target, or at target one, move the stop to breakeven — and record the column he doesn't publish: what price did *after* each breakeven exit. He says being taken out at breakeven and then watching the target hit happens to everyone and the correct response is to do nothing about it; the point of the column is to find out, on your own data, how often it actually happened to you.

Chapter 11 — Risk and Position Sizing

In this chapter: the arithmetic he teaches more often than anything else — what fraction of an account may be lost on one trade, the formula that turns that figure into a quantity, the risk-reward minimums he enforces, what he says about leverage, the daily and total loss limits above the per-trade number, and when he moves size up or down.

11.1 Why the arithmetic decides everything

Technical analysis comes first, because someone who can't read a chart has nothing for risk management to protect. But if you don't follow risk management, everything above it is of no use — quadrant two of the framework: technicals, risk management, psychology, life management, all four required before a trader can earn.

The reason he puts arithmetic above the chart is a claim about the shape of outcomes. Every result is one of five buckets: big profit, small profit, breakeven, small loss, big loss. Small losses eat small profits and breakevens are zero, so once big losses are removed the only thing

funding the account is the big profits — the single bucket you must eliminate is the big loss, not the small ones. He attaches a correction: risk management is compulsory but not sufficient — with no big profit in the book you're left with zero. The recurring analogy is the casino, which earns more than the gambler because of maths and money management, not prediction.

He nominates position sizing as load-bearing: the single most important thing in the entire stock market — position sizing, not the stop loss, is what saves you. Professionals decide their risk first and their profit afterwards; if the capital is gone you won't get the chance to take the next trade.

11.2 Risk per trade: the number, and why it keeps moving

Risk per trade is the fixed fraction of the account you decide in advance you will not lose on one trade — basically the amount you'll lose if the trade goes against you.

His first substantive answer, in 2020, comes from a loss-streak calculation: his figures show a three-loss streak roughly every eight trades, a five-loss streak every thirty-two. Run those against a large per-trade risk and the account dies — 30% per trade leaves you penniless within eight trades. Against that he reports the institutional benchmark, never risk more than 1%, endorsed for accounts above roughly 10 lakh;

below that, 1-2%; for himself, 3%, because he judges his own win rate at 60:40.

That cap didn't hold. In 2022 he gave 3-5%, on the ground that 1% is too small for the Rs 20,000-to-Rs 10-lakh accounts his audience trades. By 2024 the drift had become an explicit sliding scale by account size — 1% on a \$100,000 account, 2% on \$10,000, 5% on \$100 — because a small account is very difficult to grow whereas 1% of a large one is already meaningful. From 2025 the numbers tighten again, derived from the daily limit rather than chosen alone: 1-2% per trade so two or three trades can't together breach a 7% daily cap. A beginner with patience should risk 0.5%, "a little fast" against 0.5% "slow but steady".

The range is wide — 0.5% to 5%, with 7.5-8% named once — and he never announces a revision. Read as conditional rules, most of it resolves: higher figures scoped to very small accounts and his own higher-win-rate claim, lower ones to large accounts, funded accounts and beginners. One clarification he repeats: the percentage applies to the size of the loss, not the capital deployed — on Rs 1 lakh, 5% means a Rs 5,000 stop loss, not a Rs 5,000 trade.

Editor's note — why a fixed percentage is the standard The scheme he describes is fixed-fractional position sizing, and the "1% rule" he attributes to institutions is its common retail expression. Its defining property is that losses shrink the bet automatically: after a 20% drawdown, 1% of equity is a smaller absolute amount, so the account decays geometrically and cannot in principle reach zero from stop-outs alone — which is also its cost, since recovery is slow for the same reason.

11.3 The formula, and what it forbids

The sizing rule is stable across the whole run of videos: quantity equals risk per trade divided by the size of the stop loss, both expressed in money. Lot size is the variable, not the risk — a small stop lets the lot be bigger, a big stop forces it down. He treats the output as a ceiling and tells viewers to buy less than it.

The forbidden move is the mirror image. If the logical stop comes out bigger, reduce quantity rather than tighten the stop. On a trade with an unusually wide valid stop he names exactly two options — don't trade, or reduce quantity — and when even reduced size won't bring it inside the cap, the trade is disqualified.

Run the formula the other way and it licenses size. When the stop is very small he increases quantity a lot, because risk per trade stays the same

even at double or triple the size — the most extreme case is a forex trade where a fixed \$500 risk divided by a two-pip stop produced seventeen lots, which he says is what leverage is actually for. The caveat is bearability: don't size up so far that you couldn't bear the loss.

Two structural limits interrupt the formula. The lot system: where the instrument trades in fixed lots you can't tune quantity finely — the only fix is more capital. And contract size: because gold's lot is bigger than a currency pair's, take half the lot size in gold and silver.

Since roughly 2024 he's stopped asking viewers to do the arithmetic at all: never place a single trade without a position-size calculator. Set the stop loss level first, enter the amount you want to risk, let the tool compute the quantity. The lot size is always an output, never an input.

11.4 Risk-reward: the floor, the default, and the two families

He defines the ratio by worked example — a Rs 5 stop against a Rs 10 target is 1:2 — and calls it the retail trader's edge.

The floor moved once, early, then held. In 2020 he set 1:1 as the absolute minimum. From January 2021 the floor is 1:1.5 and trades below it must never be taken; in April 2022 he stated the change explicitly, saying he'd stopped taking 1:1 trades; it recurs essentially unchanged for four more

years. It's a habit rule as much as an arithmetic one: not below 1.5, because "the habit and the quality get spoiled".

Above the floor, 1:2 is the working default across instruments and years; beginners start there and move to 1:3 about six months later. For himself, a pro trader's job is to stretch further, and he always tries to pull his trades to 1:3 — there's only one way to turn a small account into a big one, hold your winners for 1:3, 1:4, 1:5.

The most important qualification is that the ratio doesn't override the chart. The target is counted only up to the level where support sits; the best method is the ratio method combined with the logical method, and you must have both. He sets whatever ratio the chart's levels justify, treating the ratio as an output of the level rather than an input. He doesn't always keep to it — in 2025 he placed a stop above a wick rather than the genuine location, saying you sometimes have to do that to maintain risk-reward. Treat never-shrink-the-stop as his stated doctrine rather than his uniform practice.

Underneath the ratio sits a claim about win rates. He splits strategies into two families — high win rate and high win size — treating the choice as a design decision, not a quality ranking. On the win-size side, 1:3 stays profitable at three wins in ten. The combined test is both conditions together: a win rate above 50% with a risk-reward of 1:1.5 to 1:3 is a good strategy, win rate alone is not the test. His own view changed — in January 2026 he says he used to believe a trader must have win size, and now accepts traders who win on win rate alone are also making money. The most consequential application is funded-account trading, where he

inverts the teaching — fix the ratio at 1:1 or 1:1.5 and never "play the risk-reward game" ([Ch. 12] covers why); what matters here is that he states it as a deliberate exception.

Editor's note — the ratio and the hit rate are one number, not two

His two-family framing is the informal version of expectancy: average result per trade equals (win rate $\times$ average win) minus (loss rate $\times$ average loss). Because the terms multiply, a strategy is defined by the pair and not by either half — which is why "50% at 1:2" and "40% at a wider ratio" describe the same idea.

11.5 Leverage: a question he says is the wrong question

Leverage is borrowing from the broker. SEBI's phased withdrawal of intraday margin left brokers giving roughly five times where they used to give around fifty; offshore, forex brokers offer 100, 200, up to 500 times.

The caps he states move: never accept beyond 500x; later, never above 1:200; later still, 1:30 is enough and 1:50 the maximum. These aren't all reconcilable, and he flags one himself — immediately after capping crypto leverage at 5-10x he admits he sometimes trades 25x, then restates the cap without addressing the gap. The mechanism he returns to is the multiplication of a normal move into an abnormal loss: at 50x a 1%

adverse move destroys 50% of the account, and the problem shows up in the ordinary pullback rather than a crash.

The resolution, stated most cleanly in 2026, is that the leverage question is itself the wrong question. Asked what leverage to use, he says the real question is how much risk to take — he doesn't decide leverage directly at all, he starts from how much his risk should be and lets everything else follow. There's only one variable you have to control, quantity — availability is not permission, the leverage the broker allows is not the size you should take. Borrowed money outside the broker relationship he rules out — never take a loan or debt to trade.

11.6 The limits above the trade: daily loss and drawdown

Per-trade risk is the innermost of three limits. The one he states most often, and calls the most important rule of risk management, is a count rather than a percentage: two stop losses in a day and the day is over. It appears essentially unchanged from 2020 to 2026, and he applies it against his own judgement — once two stops are hit he won't take even a god-level quality trade. The count is of stop losses, not losing-feeling trades — a break-even second trade doesn't count. The count isn't uniform — one for beginners, two in stocks and one in intraday options — and in 2026 he generalised the variation into a rule: it can be one, two or three as you decide, but it must be fixed in advance and not broken. He puts his own adherence at about 80%.

The money version he calls risk per day: a fixed daily loss amount you set and stop at once it's hit, derived from the per-trade figure and trade count — two trades a day, so risk per day equals two times risk per trade — and gives 5% as the ceiling. Other figures appear (7% as a hard cap, with the admission the real standard is 5 and he raised it as leniency), but the consistent element is the shape, not the number: a pre-set daily figure, a hard stop when it's reached, and no attempt to recover it in the same session.

Above the day sits total drawdown, mostly from rule sets he designed for funding challenges rather than his own trading: a 5% daily cap with a 15% maximum drawdown. His remedy when a trader approaches the drawdown limit is to reduce position size, not trade more aggressively to recover; trailing drawdown mechanics belong to [[Ch. 12]].

His 2020 multi-day arithmetic shows how the limits interact: at 3% per trade, one stop costs 3%, two in a day costs 6, two consecutive full-limit days cost 12, three cost 18 — at that point he says to stop trading. He adds a behavioural circuit-breaker: a trading plan needs a break system to break a losing streak before it gives back months of gains, with the break length matched to the number of losses — four losses means at least a four-day break — and the same rule applies to winning streaks, where the urge to size up dramatically is the trigger.

11.7 When size moves: adding and cutting

The most repeated sizing instruction after the formula itself is directional: never put more money into a losing trade, always put more into a winning one. The negative half is absolute — never increase quantity while the position is in red, that's averaging, a habit, and a losing strategy. The positive half he calls pyramiding: adding to a trade that's already winning so it pays two or three times more without raising the risk by the same amount.

The mechanism that makes pyramiding risk-neutral is the stop, not the entry. When he adds, he tightens the stop for the whole position, because with doubled quantity he can't carry the same price distance as risk — ten lots with a \$10 stop is the same risk as twenty lots with a \$5 stop, and shifting the stop when quantity doubles is mandatory. He's careful about the claim, admitting that on a trade that went from ten lots to forty he did increase risk somewhat.

The complementary technique is entering small first — probing, credited to Jesse Livermore: enter with a small position, add only if the trade goes your way, otherwise accept the loss. The trade-off, stated openly, is that halving the first entry turns a big win into a medium one — the payoff is a calendar shape rather than a per-trade edge, plus a psychological one: half quantity is what lets you sit through the tricky pullback.

Size comes down for a longer list of reasons than it goes up, and most are about the trader rather than the chart: after a losing sequence, while

travelling, when volatility rises, when restarting after a break. He states the policy as raising risk after profits, not after losses — the opposite of what most people do. Increases are conditional — on rare high-win-rate setups appearing once or twice a month he doubles quantity, calling this the other half of risk management, only after a strategy has produced a green P&L over months of live trades.

Against all of that sits a rule he calls the biggest secret in the industry: never increase your risk per trade as the account grows — if anything, if you're up on the day, decrease it. His standing rule after his largest reported loss: quantity must always be increased slowly and never taken heavy, no matter how large the account becomes. He doesn't claim perfect consistency — he's justified a size increase on a day when he'd lost the day before.

11.8 The cap that is not arithmetic

Running alongside every percentage is a second constraint he treats as binding independently: the size you can hold without your judgement degrading. Position size must stay inside your mental capacity, not your capital — a size that's affordable but emotionally unbearable leaves a depression you can't recover from even if the money comes back. Risk only the amount you're emotionally comfortable with.

The evidence is his own. He deliberately didn't risk \$40,000 on a trade even though he could afford to, because at that size his heart would race

and he'd cut the trade — the proof that you sized comfortably is that when the trade works you can hold a large profit instead of cutting it. The reverse diagnosis for others: people get stopped out at the pullback because their quantity is too big for them to sit through the drawdown.

The procedure for finding the number is not a calculation. Say the loss out loud in currency terms and keep cutting quantity until the figure is one you can actually accept — the answer is a quantity, not a percentage. As a pre-trade rule: think negatively first, assume the stop will hit, calculate exactly how much you'd lose, and only then take the trade. Where his percentage rules and his comfort rule disagree, he consistently takes the smaller of the two.

What he doesn't say about this

- **He never publishes a reconciliation of his own numbers.** The per-trade figures span

0.5 to 5 percent, with 7.5-8 percent named once, and he never states the revision as a revision.

- **No method for aggregating risk across simultaneous positions.** He advises holding no

more than two trades at a time while allowing himself three, and doesn't say whether the per-trade cap applies to each separately. Correlation is addressed only anecdotally.

- **Costs do not appear in the sizing formula.** Brokerage enters once, as a reason not

to take a ratio below about 1:1.3, but the quantity calculation is always risk divided by stop distance, with no allowance for commission, spread or slippage.

- **The win rates carrying the arithmetic are his own claims, not verified figures —**

the 60:40 justifying his 3%, the seven-in-ten from option selling — no backtest output is shown.

- **No adjustment for the realised loss exceeding the planned one.** He acknowledges it

happening, but there's no sizing correction for gap or liquidity risk in the formula itself.

Chapter summary

- Risk management is his second quadrant, after technicals and before psychology, and

position sizing is the single most important element within it.

- Risk per trade is the fraction of the account you decide in advance you won't lose;

figures range from 0.5% for beginners through 1-2% as a standard to 3-5% for very small retail accounts, on a sliding scale by account size.

- Quantity equals risk per trade divided by the stop loss, both in money; when the stop

is too wide you cut quantity or skip the trade, never tighten the stop to fit.

- Risk-reward has a floor of 1:1.5, raised from 1:1 in 2021-22, with 1:2 the working

default and 1:3 the stretch he aims for himself — but a real price-action level always overrides the round ratio.

- Win rate and win size are the two families of strategy, and either can pay.
- Leverage is the wrong question — start from how much risk to take and let quantity, and

therefore leverage, follow.

- Above the trade sit a daily stop — two stop losses and the day is over, or a pre-set 5%

risk-per-day figure — and a break system for losing streaks.

- Add only to a winner and only with a tightened stop; never add to a loser; never raise

risk simply because the account has grown.

- The percentage is a ceiling, not a target: size must also stay inside what you can hold

without cutting early.

Try this

The spoken-loss sizing drill, done the night before. Take the setups you intend to trade tomorrow. For each, place the stop where the chart justifies it, then say the resulting loss out loud in currency terms and keep cutting the quantity until the number is one you can genuinely accept. Set your risk per trade by account size and pre-calculate tomorrow's quantity and stop before the market opens. Then, before each entry, assume the stop will be hit and check you're still comfortable with the figure.

Chapter 12 — Prop Firms and Funded Accounts

In this chapter: what a funded account is and how the firm makes money; the rules that actually end accounts (drawdown, trailing drawdown, consistency clauses); the deliberately different risk-reward posture on someone else's capital versus his own; who should and shouldn't take one; how his own position shifted between 2023 and 2026.

No funding company is named anywhere in this chapter. Several source videos carried commercial arrangements; what survives here is the teaching, not the pitch.

12.1 What a funded account is, and what the firm is buying

A prop firm gives traders capital after they pass an evaluation, splitting profits — often quoted as 80-20 in the trader's favour, improving toward 90-10 at higher stages. Challenges come as instant funding, one-step, or two-step. He's direct about where the firm's money comes from, because his risk advice descends from it: two revenue sources — copying its most profitable traders at multiplied size on the firm's own book, and the

challenge fees themselves, since by his estimate roughly 90% of buyers fail. He argues the firm's true exposure to any single trader isn't the headline account size but the daily drawdown cap — the most that trader can lose in a day.

Editor's note — the fee as a purchased option He treats the challenge fee as the trader's entire downside — a small, capped premium bought against a larger uncapped-in-your-favour outcome. An option that expires worthless is the *expected* outcome for most buyers, which is exactly the 90% failure rate he quotes on the other side of the same ledger.

12.2 The rulebook: the limits that actually end accounts

He ranks rule knowledge above market knowledge — a challenge tests discipline and professionalism, not analysis. You must properly understand four things: daily loss limit, maximum drawdown, profit target, breach conditions. The numbers below are illustrations of *kinds* of rules, not universal thresholds — he says so himself, since they differ between firms.

F12.1 — Funded-account rule families

Rule family	What it is	Typical threshold	Hard breach?
Maximum drawdown	Absolute floor, not a warning line	6-8% of account size	Hard
Daily drawdown	Cap on a single day's loss	Commonly 3%; three separate 2% days can still breach a 6% total	Hard
Trailing drawdown	Never falling more than X% below your <i>highest</i> equity, not starting balance	5% overall, sometimes a separate ~4% intraday version	Hard — "the rule most traders lose to"
Stacked-trade cap	Limit on repeated same-direction positions	Five, in rulebooks he shows	Not stated
Stop-loss window	Stop must be attached within a stated time	1-3 minutes	Stated as a breach if missed
Weekend restriction	No weekend trading/holding, bitcoin included	Flat prohibition	Not stated
Consistency / best-day rule	Your best day must stay in proportion to the rest	~15% consistency	Not stated

Rule family	What it is	Typical threshold	Hard breach?
First-payout cap	Ceiling on the first withdrawal	20% of account size	Not stated

Editor's note — why a peak-referenced limit behaves so differently

On a \$100,000 account with an 8% trailing limit, the floor starts at \$92,000. Take the account to \$110,000 and the floor ratchets to \$101,200 — a trade that gives back \$9,000 of *unbooked* profit ends the account even though the original stake was never touched. Floating profit isn't yours to risk; a strategy that earns from a few large winners held through deep drawdown is structurally incompatible with the rule. Same high-water-mark logic as hedge-fund incentive fees, except a fund manager below the mark still has a job.

12.3 Two accounts, two rulebooks: the risk-reward split

Trading real capital and trading a funded account need two different rule sets; he tells viewers to read any strategy twice. On his own capital he stretches — 1:3 to 1:4. On funded capital: never play the risk-reward game — targets of roughly 1:1 to 1:1.5, explicitly not 1:2 or 1:3 (the exact ratio drifts between videos — 1:1, 1:1.5, sometimes 1:2 shown live — but the *direction* never does: always smaller on funded than personal capital).

Two reasons: stretching risks the trailing-drawdown rule taking you out on the way back; and whose money it is — a 1:1 win goes in your pocket, the loss doesn't come out of it. On funded accounts, win rate matters more than win size — the reverse of his own capital.

Editor's note — the break-even arithmetic behind "win rate over win size" He asserts 47% at 1:1 is enough to make meaningful money on a funded account — at 1:1 gross, break-even is 50%, so 47% is slightly negative before costs; read as encouragement, not arithmetic. The robust version is about variance: a high-hit-rate, low-payoff distribution produces far shallower equity dips than a low-hit-rate, high-payoff one — and a peak-referenced drawdown limit prices *dips*, not returns. That's why the same edge can pass in one configuration and breach in another.

Position sizing: 0.5-1% risk per trade, never increasing as the account grows. His second "hack" for passing a challenge: break risk into smaller pieces — where you'd risk \$1,000, try \$250 — because smaller risk buys more attempts before a breach.

Trade management: always book profit, cut at target, close the day. Never trail into the trailing-drawdown rule. His clearest illustration against himself: the silver trade that made a crore couldn't have been held on a funded account — the trailing drawdown would have emptied it on the pullback.

12.4 Who should take one, and in what order

Competence gates it, not enthusiasm: a new trader "will lose it with near certainty". If you're losing from lack of skill, no funded account of any size helps. The trader prop firms actually suit is the one whose technicals already work — whose 1:2/1:3 trades reach target — where sizing is the problem the funded account solves. Behaviour is the second gate: an overtrader or revenge-trader shouldn't do prop trading regardless of cost. His readiness test: take one once your overtrading and revenge trading have already stopped.

His ordering advice is genuinely inconsistent between videos — sometimes smallest plan first regardless of skill level, sometimes matched to profile (beginner → smallest, break-even → middle, already-profitable → large). The common thread across versions: start small, earn the right to scale. Once passed, his routine is deliberately unambitious: one trade a day; if it loses, close and come back tomorrow.

Editor's note — the arithmetic under "one trade a day" At 0.5-1% risk per trade against a 3% daily cap, one trade a day means the daily limit can't be reached at all — it would take 3-6 consecutive full losses in one session, which the rule forbids by construction. This is the standard structure of a hard risk budget in any institutional book: size per-event so the aggregate limit is only reached by a run of events, never a single decision.

12.5 Judging a firm, and how his own position moved

Between 2023 and mid-2025 his position was close to blanket rejection, stated strongly across at least six videos: "most funding challenges are scams"; the business model *requires* candidates to fail, since fees fund promoters' commissions; by June 2025, "not a single company giving out funded capital was good... so far". He disclosed his incentive at the same time — anyone promoting anything earns a commission.

From September 2025 the videos reverse — he begins walking through rulebooks, comparing firms, recommending one. He names the reversal directly: he used to say funded accounts weren't needed and didn't trade them himself, then changed course to understand what his subscribers feel.

Editor's note — reading a reversal like this Both positions are his, roughly two years apart, and the later videos are commercially connected in a way the earlier ones weren't. What did *not* change: his account of the industry's economics — 90% failure, fees as revenue — is identical on both sides. What changed is his conclusion about whether a subset of firms is worth using, and his own participation. A reader can accept the mechanics in §12.2/12.3, verifiable against any firm's published rule sheet, while forming an independent view on the recommendation, which is not.

His catalogued complaints are worth keeping regardless — they describe failure modes, not specific firms: hidden rules changed after the fact; accounts cancelled under elastic labels like "toxic flow"; the IP-violation clause used to block payouts on the grounds that a trader logged in from a different device; interview-based verification that gives the firm licence to take the account on any pretext. His due-diligence tests are mostly disclosure proxies: rules visible on the dashboard up front, evidence past winners were actually paid. ****The jurisdictional point matters most****: if a funding company wrongs you, there's no SEBI to complain to — it's an international market, so you have to vet the firm yourself.

What he doesn't say

No workable test for legitimate vs. scam. He admits in April 2025 he doesn't know which firms are genuine. The due-diligence criteria are all disclosure proxies, none testing whether a firm will honour a large, unexpected withdrawal.

The 90% failure figure is unsourced — his own description is "a round rhetorical figure".

The reversal is described, not fully explained. He states the change of course but never revisits the earlier specific claim that any fee-charging model "is not right" — which every product he later walks through is.

No tax treatment for funded-account income.

Chapter summary

- A funded account is firm capital after evaluation, typically an 80-20 split; the firm's revenue is copying its best traders at multiplied size

plus the ~90% failure-fee pool.

- Rule intelligence outranks market intelligence — know the daily limit, max drawdown,

profit target, breach conditions before trading any account.

- Trailing drawdown is measured from your equity *high*, not starting balance — given-back

open profit ends accounts.

- Funded capital gets a different rulebook entirely: fixed small size, 1:1-1:1.5 targets,

win rate over win size, book don't hold.

- Take one only once you can already trade and have stopped overtrading/revenge trading; start small and earn the right to scale.
- Vet the firm yourself — there's no regulator to appeal to.

Try this

Translate the rulebook before you trade it. Take any funded account's published rule sheet and write down, in your own words as numbers on your account size, the four things he says you must understand: daily loss limit, maximum drawdown, profit target, breach conditions. Convert each percentage into rupees or dollars, as he does turning a 6% maximum drawdown on a \$5,000 account into \$300. Then separate soft breaches from hard ones — the hard ones are the numbers you actually trade against.

Chapter 13 — Options, Forex, Gold, and Crypto: Market-Specific Mechanics

In this chapter: what changes when the instrument changes and what he insists does not; options — contract mechanics, strike selection, the buyer's decay problem, the seller's margin problem, and his event-day straddle; the Indian equity/index/futures layer; forex as a 24-hour, broker-fragmented market, including how he says Indians reach it; gold, his single largest instrument by video count; crypto, entered in 2021 and largely retreated from by 2025; and the smaller satellites — crude, silver, US indices.

No broker, exchange platform, funding company or charting service is named in this chapter. Sections on offshore forex and crypto legality report his own on-camera statements — mostly without citation to statute — because he says them often and they shape what he teaches. They are not endorsed, and nothing here is legal or tax advice.

13.1 The front end changes, the back end does not

His standing position: technical analysis is identical across markets, so a book about forex is useful for stocks. What differs is only the "front end" — lot sizes and pips in forex, leverage in crypto, contract cycles in futures, moneyness in options — while the analysis itself stays the same. In practice he names many exceptions: breakouts work in equities while forex wants traps; reversal patterns work in Indian markets because one national exchange means one chart, and fail offshore because every broker publishes its own price.

Editor's note — one market has a single chart, the other does not

Indian equities trade on one exchange's order book, so every participant sees one printed price. Spot forex and gold have no central exchange — each broker streams its own price. The 2015 Swiss franc de-peg is the extreme case: EUR/CHF prints diverged by hundreds of pips across brokers within a minute. That's why he wants price to touch or trap a fifty-percent zone rather than an exact number offshore.

The one instrument difference he derives rather than asserts is timeframe. A six-hour Indian session prints roughly a quarter the candles of a 24-hour market. Hence: forex works on 15-minute and up, never 5-minute; Indian stocks can drop to 3-minute because the session is only six hours. He also names the 24-hour clock as the single biggest psychological danger of forex and crypto — a trade is always available, so overtrading becomes

the problem to solve. His own remedy: pick one session that fits your existing schedule rather than sitting from 6am to 1am.

13.2 Options: the contract, strike selection, and the buyer's decay problem

He introduces options as a derivative, with CE/PE notation and European-style Indian contracts. He trades only index options, not stock options, since stock options have poor liquidity and can't scale; by 2026 he narrows further to Nifty specifically.

His moneyness test has stayed the same for six years: read the contract name as a present-tense sentence — true now means in the money. His single most-repeated piece of options advice is to buy in the money, since an ITM option doesn't lose immediately when the market turns, giving room to cut at the stop. His case against far-OTM buying is an asymmetry argument — roughly 10% gain when right against 50% loss when wrong — not a prohibition; OTM is permitted only on rare "super setups" with small position size. The rule he treats as actually binding is the exit, not the entry: whichever strike you buy, you must be in the money when you leave, by roughly fifty Nifty points — his answer when students note he himself buys OTM.

Editor's note — the five Greeks, briefly Delta: premium change per point of underlying. Gamma: how fast delta itself changes, largest near expiry. Theta: premium lost per day to time. Vega: premium change per point of implied volatility. Rho: sensitivity to interest rates, negligible on short-dated contracts. His "exit in the money by fifty points" instruction is really a delta requirement stated informally.

He calls an option self-destructing: theta runs negative regardless of direction. His "rule of 33 and 67": a buyer taking every opportunity loses roughly two-thirds of the time, profiting only on decisive trending moves. Speed matters as much as direction — the same fifty-point move pays far less booked slowly than booked in one fast candle. His day-of-week strike map: at the money Monday, strictly in the money Wednesday and Thursday, since theta decays fastest late in the week.

Because no stop protects a premium against a gap, his rule is simply to keep quantity small — never deploy more than 30% of capital into premium, tightened to 15-20% on very good days. A genuine option stop is at least 30% of the premium, so his capital floor for buying at all is roughly Rs 20,000-40,000. He doesn't put option stops on the system — he cuts by hand, because the premium level meaning "I was wrong" is a different number at 10am than at 2pm.

Editor's note — why a premium stop behaves differently from a price stop An option's premium is a function of four moving inputs at once — underlying, time, volatility, delta — two of which keep moving while you sit still. On 4 June 2024 (India's election counting day), Nifty fell roughly 6% intraday and put premiums multiplied several times over faster than the index moved. A resting premium stop set the previous afternoon would have executed at a price bearing no relation to the index level it was meant to protect against.

Selling. His counting argument: the seller wins on two of three market paths (favourable move, or sideways), the buyer on one. The trade-off is win rate versus win size, with a rough (self-labelled, not measured) 70% hit rate justifying even a 1:1 payoff. Naked selling is "a big no" — always hedge or stop, since the loss is theoretically unlimited. A hedge does two separate jobs he keeps distinct: protecting an existing position, and freeing margin (SPAN + exposure split) — buy the cheapest OTM hedge for margin relief, a hedge with real premium value for actual protection.

Editor's note — why a small option releases a large amount of margin SPAN revalues your whole position across a grid of scenarios and charges the worst single outcome. A naked short has an unbounded worst case; a bought far-OTM option that's worthless in almost every cell caps the tail without touching the ordinary scenarios. His two contrary hedge instructions aren't a contradiction: the cheap hedge satisfies the exchange's worst-case model; a real-premium hedge is what actually limits the loss you'll take on an ordinary move.

Within selling he distinguishes directional selling (his own game — sell the ITM put instead of buying the call, since a delta trade needs real premium) from non-directional structures (strangle/straddle, filtered by ADX — never buy while ADX falls, sell when it does). He does not treat buying and selling as a choice: the best approach mixes both, roughly 60/40 selling to buying, because selling works in any condition while buying needs a trend.

13.3 Event days: the rise and retirement of a budget-day straddle

One structure gets six years of dated, public revision — the long straddle on Indian budget day, buying an at-the-money call and put together. The 2022 version is fully specified and it lost that year — the market closed near its open. In January 2023 he retires it outright: viability depends on which weekday the budget falls, and by Wednesday/Thursday there's too

little theta left for the straddle to pay. In 2024 he brought the day-straddle back (calendar permitting) and lost again, reporting it honestly the next day. By 2025 the retirement is general: two trades planned, entries only on an 11:00 high/low break.

Editor's note — the volatility half of the event trade A long straddle needs the underlying's move to exceed the combined premium. Before expiry the position also carries vega, largest for at-the-money contracts with time left, which is why implied volatility collapses the instant a scheduled announcement lands regardless of its content — he shows this live when a big green candle produces no rise in the call premium.

He runs a separate, unrelated straddle around individual stock results: buy call+put at the strike nearest spot in a pre-result stock with no momentum yet, hold only a few days (not to expiry), exit by Friday — the overnight gap risk that scares other traders is exactly what pays this one.

13.4 The Indian layer: equity, index, futures

Equity is where he tells almost everyone to start — cheap, forgiving, no theta drama. Rs 10,000 is enough capital, with a realistic target of turning it into twelve to twenty thousand, not a lakh. His progression: equity, then option selling, then option buying, then forex. The index he defines

plainly — Nifty is not a company, just fifty companies weighted into one number — and his instrument advice is to pick exactly one index rather than following three.

Futures he treats as the swing instrument: three-month contract cycles, always trade the near month for depth, roughly 4-6x leveraged, not for beginners with small capital. He states the upside multiplication plainly (Rs 5,000 cash profit becomes Rs 30,000 in futures) without running the same arithmetic on the downside.

Editor's note — the other half of the leverage arithmetic His own figures (roughly Rs 1,16,000 margin against Rs 6.5 lakh outright) put the margin at about 18% of contract value — so a 3% adverse move, ordinary for a large Indian name, costs about 17% of posted capital. He also mentions rollover cost without decomposing it: the price gap between contract months is the cost of carry, paid again every month held.

He prefers futures over options for multi-day holds specifically to avoid theta, and analyses futures trades on the spot/index chart, using the futures chart only to convert the move into a rupee stop. His defining hazard for the whole Indian layer is the overnight gap — mostly disastrous, occasionally an opportunity to buy the same idea cheaper.

13.5 Forex: mechanics, sizing, and where he changed his mind

Forex is decentralised, OTC, running through a chain — banks to liquidity providers to brokers to traders. Broker type is, in his own words, the most important part of forex trading: an STP broker passes your order through and earns from spread, unaffected by your result; a non-STP (dealing-desk) broker takes the other side itself, so your loss is its profit. His instruction is always go STP, and he warns against chasing a cheap broker for lower cost or higher leverage — safety should be the priority.

Editor's note — what you actually own A broker passing orders through is running an *A-book*; one taking the other side is running a *B-book* — most firms run both, routing unprofitable clients to the B-book undisclosed. A retail forex "trade" is almost always a bilateral contract with the broker, not a purchase of currency.

Pips: fourth decimal digit, with a November 2023 video explicitly retracting his own 2022 teaching on the calculation as "outdated" — a rare on-camera correction. Lot size ratio he asks students to memorise forever: 0.1 lot $\approx$ \$1/pip, one standard lot $\approx$ \$10/pip.

His sizing approach changed for the better. Early version: a fixed lot-per-dollar table ($\approx$ 1% risk). Later version inverts it — fix risk in currency first, then divide by stop distance in pips to get lot size, varying size to

hold risk constant. He reframes the common question entirely: how much leverage to use is the wrong question — the right one is how much risk.

Editor's note — margin is not risk $\text{lot size} = \text{money willing to lose} \div (\text{stop distance in pips} \times \text{pip value})$. Leverage doesn't appear in that expression — it determines *margin* (broker collateral), not risk. Two traders with identical size and stop have identical risk regardless of leverage setting; the only thing leverage changes is where the *broker* liquidates you if the account runs out of collateral before your stop is hit.

His pair list has narrowed steadily — from roughly eight majors plus metals (2022) to just four by late 2023, because ten to fifteen instruments "will not work." He uses correlation as a confirmation filter, but by 2026 warns never to trade on cross-instrument correlation at all, since fundamentals can break the assumed link at any time. His own session window is consistently 12:30pm-9pm India time, favouring roughly 4:30-8pm. Two absolutes: the stop always goes in the system, never held mentally; and he keeps an event calendar filtered to high-impact, relevant-currency releases only.

13.6 Forex access from India: his claims, reported not endorsed

Every claim in this section is his, stated on camera repeatedly, mostly without citation to statute. None is verified here.

His baseline: forex trading is totally illegal in India. His reading: FEMA bans taking India's money outside the country, so the line is bank-account-to-bank-account — a transfer between two Indian accounts is fine, a transfer into a foreign forex company's account is not. He backs this with his own experience: a personal bank account closed after a deposit-linked transfer from his overseas trading account, still not reopened, which he says is why he relocated to Dubai. His workaround is peer-to-peer funding — money lands with a registered Indian citizen or company rather than the forex firm directly, which he argues is legal because no money technically left the country; this is his own reasoning, not endorsed by any regulator. By 2026 he splits capital scale: below ~Rs 25 lakh use P2P, above it become a Dubai resident with a proper entity.

Editor's note — this section is reportage, not endorsement He says forex from India is illegal and separately argues a funding route makes it lawful — those claims are not fully reconciled. What he actually reports happening to him — an account closed, money stuck in transit — is the concrete lesson: counterparty and payment risk in an unregulated offshore relationship is not a technicality, it is the risk. Anyone weighing this should take professional advice on their own residency and tax position.

13.7 Gold: the instrument he treats as its own category

By video count, gold is his single largest instrument. He calls it "not a normal stock, not an index, not a commodity — its own category," driven by dollar news, recession data, and central-bank buying. His defining characterisation: gold is "very manipulative" — it deceives, rallying as if going up then falling. He compares it to Bank Nifty: fast, long-pipped, will blow the account if lot size is raised.

His rules follow directly: always trade with a smaller lot than a currency pair — half the size. Keep the stop on the system, always — even so, he calls a \$2 stop unrealistic for gold; \$5-9 is common. Trading starts only after 10am India time, when European/US volume arrives. He backs the timing with his own time-bucketed review of one strategy: the 12:30 candle produced 1 target against 12 stops and he removed that hour

entirely; his favourite 6-7pm window gave 17 targets against 9 stops — scoped explicitly to that one strategy.

His main gold setup is built on the previous day's high/low: after 10am, when price takes out the marked level and closes back inside (which he calls manipulation/stop-loss hunting), that's the entry, against the sweep.

Editor's note — "manipulation" as a name for something ordinary

Prior-day extremes are where a large, visible cluster of resting orders sits — protective stops plus breakout entries. A probe into that cluster fills those orders and triggers a momentum burst with nothing behind it; if it was liquidity-seeking, price returns inside the range, which is his signal. This is documented "stop-run" behaviour and needs no single actor.

He is unusually candid about the strategy's misses and about his own reversals: he told beginners to avoid gold entirely in 2021, then to start with gold in 2026, without marking the change. His target sizing also flipped — "no oversized targets" in 2021 became "capture at least \$20, not \$5" by 2026, five years and a much larger account apart, unreconciled on camera. He reports his own worst outcomes candidly too — a deliberately isolated \$3,000 account blown three times and a \$5,000 account once before one attempt worked — reported as what he did on money he could lose entirely, not as instruction.

13.8 Crypto: definition, legal framing, and the phase filter

He entered crypto in 2021 admitting limited experience, drawn in because price action worked there better than he could explain. His definitions stayed simple: bitcoin as the first blockchain currency with a public, decentralised ledger; three categories — bitcoin, large-cap alts, small/mid-cap alts.

Editor's note — what a perpetual is, and its invisible holding cost

Almost all his crypto trading is in perpetual futures — contracts with no expiry, anchored to spot via a funding rate exchanged between longs and shorts every eight hours. In strongly trending 2021 markets this ran near 0.1%/8h (~100%+ annualised) — an invisible drag, the crypto analogue of the theta he explains at length for options.

On legality his framing is the mirror image of forex: he calls crypto trading "entirely legal in India," reasoning inferentially — a 30% tax announcement implies legality, and many crypto firms are registered on Indian soil, unlike forex firms. As with forex, these are his statements, not verified here.

His leverage cap has drifted across years — 10x (2021) up to 25x if funding is small, 5-10x (March 2022, admitting he sometimes trades 25x anyway), up to 50x for the experienced by mid-2023 — best read as a range rather than a rule. The arithmetic he prices out loud: at 100x a 1%

adverse move wipes a \$1,000 account; at 10x the same move costs \$100. He resolves his own drift the same way he does in forex — size from the stop's dollar cost, not the leverage multiple. Crypto is the one instrument where he's most absolute about system stops: never trade it without one, compulsory not optional.

His watchlist has narrowed the same way his forex pair list has — from roughly nine majors (2021) to bitcoin-and-ethereum-only for beginners by 2024, to a top-six-to-ten-by-market-cap rule for trading by 2026.

The single most load-bearing claim in his crypto material is the phase filter: trade crypto in a bull phase, invest (don't trade) in a bear phase, because bear-phase whipsaws hit stops that can't be managed. He's acted on it repeatedly — stopping crypto coverage through multiple bear stretches, redirecting to forex instead. By 2025 the retreat becomes near-permanent: he calls bitcoin "heavily manipulated" and gold the better instrument, and his 2026 bitcoin commentary is mostly bearish.

Editor's note — the phase filter is his strongest claim and his least tested "Trade it in a bull phase, invest in a bear phase" would change a reader's results more than almost anything else in this chapter, and it's never operationalised — he describes the symptom without a rule for spotting the phase in advance. The practical version of his own rule: watch whether *your* stops are being hit on noise, which is diagnosable from your own log without first deciding what the market is doing.

13.9 The smaller satellites: crude, silver, US indices

Crude he treats like gold — prefers the 24-hour offshore market over the domestic exchange for the same gap reason, sized slightly larger than gold since its lot needs less margin. Same top-down technique throughout the chapter: higher timeframe for trend, liquidity levels and fair value gaps on 15/3 minutes for entry.

Silver he treats as gold's shadow — check gold before trading silver, since it "behaves approximately the way gold behaves," while warning the two aren't the same trade because their fundamentals differ.

US indices (Dow, Nasdaq, S&P) he offers as an evening alternative for readers whose day is occupied — the same audience argument as forex. His volatility analogy: the Dow moves like Nifty, the tech index like Bank Nifty. On US options he's clear about the barrier (no US citizenship/passport/bank account, no access) — his stated workaround, borrowing a US-resident relative's account, is reported here only because he says it; it is not endorsed and would breach any broker's terms.

Editor's note — what "US 30" actually is A retail "US 30" or similar contract is generally a CFD written by the broker against the index, not an exchange-listed product — the identical broker-feed problem he identifies clearly for gold and forex.

What he doesn't say

- **Cost comparison across instruments.** He gives spread figures for forex and

mentions crypto fees in passing, but never puts a round-trip cost side by side across the instruments.

- **Whether his instrument-specific exceptions were tested.** "Breakouts work in

equities, forex wants traps," "sweeps don't work in Indian markets," "trap trading fails in bitcoin" — each asserted from experience, none with a sample size or period.

- **How to identify a crypto bull-vs-bear phase in advance,** rather than in

hindsight — his strongest crypto claim has no stated method for calling it before the fact.

- **The legal and tax material is unsourced.** Forex "illegal, but a funding route

makes it lawful" and crypto "entirely legal" both rest on his own inferential reasoning, not statute; his claim that international profits attract no tax contradicts his own "other income, declare it" guidance elsewhere.

- **Why he keeps or leaves a market.** The crypto retreat and the shift toward futures

and gold are documented, but the decision rule behind reallocating capital is never stated.

Chapter summary

- The analysis doesn't change with the instrument; the front end does — lots and pips

in forex, leverage in crypto, contract cycles in futures, moneyness in options.

- The one derived (not asserted) difference is the clock: a 24-hour market prints ~4x

the candles of a 6-hour session, hence forex/crypto on 15-minute-plus, Indian equity down to 3-5 minute.

- Options: buy in the money by default, but the rule he treats as binding is exiting in

the money, not entering there.

- Selling wins on two of three paths and pays for it with tail risk — naked selling is

ruled out, every short carries a hedge or a stop.

- Offshore instruments have no single chart — broker feeds differ, so levels are zones

and stops are set from the execution feed, not a drawn number.

- Gold is its own category: manipulative, fast, half a currency pair's lot size, stop

always on the system.

- In crypto, leverage is the wrong unit — size from the stop's dollar cost, cap

beginners at 10x, never hold without a system stop.

- Crypto is phase-gated in a way nothing else here is: trade the bull phase, invest in

the bear phase, leave it alone between.

Try this

Size by the money, not the multiple. His crypto sizing procedure: enter the stop price, read the exact rupee/dollar loss the platform shows, lower quantity until that number is acceptable — if it won't come down far enough, skip the trade. Run it on a demo account across an index option, a

gold position and a bitcoin position, holding the money loss constant and letting lot counts differ.

Chapter 14 — Trading Plans, Journaling, and Routine

In this chapter: why he insists a plan is written before the session, what a plan must contain, the shape of his day, what goes in the journal, how review converts writing into change, and the testing regime — backtest, forward test, demo — beneath all of it.

14.1 Plan or gamble: why the process exists at all

Gambling is putting money on a random number and trying your luck; genuine trading is planning something in advance and acting when it happens — his test for whether a trade counts as trading at all is whether the plan existed before the event or was fitted to it afterwards. Plan your trade, then trade your plan. If you don't know your win rate or edge, you're gambling, and most people know neither.

Two consequences shape everything later in the chapter. First, a day is judged by whether it followed the plan, not by the outcome. Second, the plan grants permission to do nothing — if the planned condition doesn't occur, you don't do the opposite, you simply do nothing.

Editor's note — pre-commitment, and where the idea shows up elsewhere Deciding in advance is valuable because the mind freezes in the live moment. The general name is pre-commitment — binding a future decision while calm, because the future state is known to be worse at judgement. The WHO Surgical Safety Checklist (2008, eight hospitals) is the studied case: a fixed order of confirmations before incision, containing no new medical knowledge, that reduced complications and deaths. Same mechanism — written when nobody is under pressure, consulted when everybody is.

14.2 The trading plan as a document

His fullest version has seven components: technical analysis (entry and exit settled before the trade runs); written rules; wall-posted guidelines phrased *positively* — the behaviour you want, not the mistake you make; a motivation system; a break system; an improvement system; and, called most important, **disaster management** — "a plan without it is worthless however good the rest is". The finished plan is read backwards from how it's drafted: disaster management at the top, technicals below.

His shorter 2025 version reduces it to four decisions: entry criteria, stop loss, quantity, exit/target — the plan simple, the entry criterion sophisticated. Before any of it: know your own trading style, gated by capital and personality — in 2026 he calls this creating a "trading identity," which by definition means saying no to all the others.

Editor's note — why "phrase it positively" isn't a motivational flourish "Do not overtrade" names no action, so there's nothing to perform at the moment of temptation; "take at most three trades, then close the platform" specifies a situation and a response, checkable after the fact. This is what decision research calls an implementation intention — an if-situation-then-action pairing, the same design behind aviation memory items and hospital sepsis bundles.

14.3 The daily cycle

Four steps: homework the night before, pre-market research, action after the open, and journaling. To trade Monday, sit down Sunday night. He caps his watchlist at four stocks, because ten can't be tracked. The plan itself takes only 10-15 minutes precisely because the analysis was already done beforehand. Session conduct is deliberately thin — he does his thinking after the close and tries nothing new once the market is open. Trading hours are themselves a rule, not a consequence of free time: fix a two-to-four-hour window in advance, and decide the trade count inside it before the session starts.

14.4 The routine around the trading

Life management (quadrant four) is not needed to *have* a working system — it's needed to *execute* one. The morning is the most specified part: no phone first thing, including checking whether the market gapped — whatever occupies the first ten minutes stays with you all day. His stated sequence: light movement, meditation, check markets but decide nothing, read your wall rules, revise the last ten days. He journals immediately after meditating, while still rational rather than emotional.

He's candid about compliance: about 60-75% of the routine, 100% only on some days — repeated two years later at 60-70%. Two mechanical rules become trading rules outright: don't trade sleep-deprived, and don't trade when not in a good mood, from any source.

14.5 The journal: emotions, not data, written live

He describes journaling wrongly for years — writing entries, times, quantities the order book already gives, never emotions. The corrected instruction is the mirror: don't fill it with stock name, time, quantity — write the emotions, because to improve emotions you have to put emotions in. ****The timing rule is firm****: journal live with the market open, not after the close — write it badly if need be, swearing at yourself on the page is acceptable. One book, two handwritings: live entries in bad handwriting, the review in good handwriting.

Editor's note — why writing during the event, not after, is load-bearing Retrospective self-report is systematically reshaped by outcome — once you know a trade lost, the reasons you reconstruct aren't the reasons you had. NASA's Aviation Safety Reporting System (since 1976) collects confidential, non-punitive incident reports for exactly this reason — confidentiality is what keeps a report accurate. Same mechanism behind his insistence the journal stay private.

14.6 The format he arrived at

For years he journaled on blank sheets and found the mind "gets lost" on an empty page. His 2025 format: one-time sections (why you want to trade, how much time you'll give it), then daily pages opening with "why am I trading today" — to gamble, to make too much money, to double capital, or for a career. Pre-trade fields: stock, setup, support, quantity, stop, target, risk, and emotion (excited/greedy/scared). Post-exit: do you feel greedy, want to trade again, want to overtrade, want to recover. He insists on a "what good did I do today" field too — confidence needs feeding as much as criticism.

The journal must be private and never shared: if you know someone will read it, you'll polish it and start writing fake things. Missing one day is fine, not the second — restart without guilt. In his 2025 format video he admits he'd written very little himself over the prior 18 months, because

his own trading is now automated and team-run — while insisting the journal remains essential for manual discretionary trading.

14.7 Review: daily, weekly, and the order book

Writing without reading back is pointless. The loop: backtest, trade on that data, journal the trades, review the journal. Daily review after a break (the relaxed self does the reviewing) — what plan did I follow, what mistakes, what did I learn, what can I do better. Weekly, on Friday or the weekend — "the most dangerous part" — reread the week. Separately he reviews the broker's order book every week or fortnight, one to two hours, going through each entry/exit individually.

The single review question is deliberate: was it my fault or not. A good loss wasn't your fault, a bad loss was one you could have controlled — never the market's fault. Compare the *size* of losses against the size of profits, don't count wins.

Editor's note — separating the decision from the result His single question — was it my fault — together with his refusal to ask why the market moved, amounts to reviewing the decision rather than the outcome. Hospital morbidity-and-mortality conferences do the same thing: ask whether care was appropriate given what was known at the time, deliberately not whether the patient survived, since correct treatments sometimes fail.

14.8 Backtesting: what it takes, and what a good result looks like

His definition is narrow: a strategy with defined rules, manually extracted into a trade-by-trade record. Two to five screenshots is not data. He logs per trade: date, entry time, day, direction, stop (currency and percentage), target, outcome, reason — in Excel, not Python, "a very long thing" for a retail trader. One strategy, one instrument, one timeframe. He never changed a rule mid-backtest to suit himself, deliberately counting marginal trades as losses.

Sample size has clearly risen over the years — "keep going until satisfaction" in 2020, to a 90-day starting minimum by 2024, to "at least three or four years, professionals have five to ten" by 2025. Read as a floor that rises with the seriousness of the use, not competing rules.

He's restrained about what "good" looks like: 55-68% win rate for a single price-action strategy over two years, expecting more is unrealistic; win rate over 50% combined with 1:1.5-1:3 risk-reward is a good strategy. He also publishes results below his own bar — a 46%-win-rate strategy with 1:3-1:7 sizing — and warns a backtested win rate in the seventies typically falls once someone cross-checks it, because stops get placed differently live.

Once a sheet exists, he filters it — time-of-entry first, then day-of-week on the surviving subset. On one gold strategy, the 12:30 entry gave one target against twelve stops and he removed that hour from his career entirely; his favourite window gave the opposite ratio. He scopes every finding to that one strategy.

Editor's note — the arithmetic of filtering, and its hazard This is a real technique with a real risk he doesn't discuss: multiple comparisons. Slice a two-year sheet into a dozen entry times and five weekdays and the best-looking subset of dozens will look good partly by chance even with no real effect — and the subsets are small (a headline figure computed from fourteen trades carries wide sampling error). The canonical illustration is David Leinweber's finding that Bangladeshi butter production "predicted" the S&P 500 with a correlation above 0.75 — meaningless outside the search that found it. The standard defence is holding back data: pick the filter on one period, test it on a period you haven't looked at. He does something adjacent (a second 90-day batch to confirm a pattern) but doesn't frame it as a defence against this problem.

14.9 Forward testing, paper trading, and demo accounts

Backtesting checks the strategy; forward testing applies it in real time to find out whether it works or you were fluking — name the setup and the exact trigger condition without taking the trade. His full sequence: understand the rules, backtest, forward test, demo account, then live.

Paper trading is where his positions genuinely diverge. On one side: beginners should paper trade one to three months before funding anything, and not start real trading at all if in debt. On the other: psychology won't come from paper trading, only real money produces it, so it's only for practising mechanics. He told one student who'd taken his course not to paper trade at all — offering a small real-money size instead. His demo-to-live gate numbers wobble within a single video — three to four months and \$200-500 in one sentence, two to three months and \$100-300 in the next. Treat this as a spoken range (2-4 months, low hundreds of dollars), not two rules.

Editor's note — what a demo account cannot reproduce, mechanically The easier-to-verify half of his scepticism is mechanical, not emotional: retail demo servers fill orders at quoted price with no slippage and no widening spread around news. A strategy whose edge is small relative to costs can look profitable on demo and unprofitable live with no change in the trader's behaviour at all. The Swiss franc depeg (15 January 2015) is the extreme real case — EUR/CHF gapped thousands of pips in minutes, stop orders filled far below trigger, and at least one retail broker went insolvent. No demo environment models that.

14.10 The break system: when to stop

Named as part of the plan itself. His most concrete version: close the day after two stop losses; a breakeven or a trailed exit doesn't count toward the two. Two failure modes bound it: never over-aggressive, never over-defensive — don't shut after one stop, don't take ten trades either. He decides the daily trade cap in advance, before any strategy work.

Longer breaks are prescribed by event, not calendar. After a big loss: stop, take a break, journal, backtest, gather data before returning — his own post-blowup break ran 15-20 days. Symmetrically, after a big profit: no trading for two or three days. One category he keeps breaking and keeps admitting to: never trade while travelling, and when he does, the position

needs a pre-set stop and target with smaller-than-usual quantity — a rule he's broken and reported on more than once.

What he doesn't say

No test for legitimate rule-change vs. rationalisation. He's emphatic rules can't change for a trade you'd like to take, and equally emphatic the plan needs an "improvement system" because markets change — no procedure distinguishes the two beyond "review weekly."

No stated minimum sample size per filtering bucket, and no answer for a backtest landing at exactly 51% — the boundary case his own "above 50" rule leaves undecided.

The paper-trading switching point is genuinely unresolved — his own numbers vary within a single video, and whether an experienced trader should paper trade at all is never stated as one rule.

The full routine is described from a full-time trader's position — he designs evening slots for people with jobs, but reports managing only 60-75% of the routine himself.

Chapter summary

- Trading is planning in advance and acting when the planned thing happens; a day is

judged by whether it followed the plan, not by outcome.

- The plan has named components beyond technicals — rules, positively-phrased wall

guidelines, motivation/break/improvement systems, and disaster management, called most important.

- The journal is written live during the session, records emotions rather than order-book

data, and stays private; review matters more than writing.

- Review asks one question per trade — was it my fault — and compares loss size against

profit size rather than counting wins.

- A strategy is stateable rules plus manually extracted data; his required history rose

from "until satisfied" to 2-4 years, with 55-68% win rates realistic.

- Paper trading builds mechanics, never psychology; the sequence is backtest, forward

test, demo, live.

- Stopping is planned like everything else — two stop losses ends the day, longer breaks

follow big losses and big profits alike.

Try this

One strategy, one sheet. Pick a single setup, one instrument, one timeframe. Extract 90 days of data by hand into a notebook, then a spreadsheet, logging date, entry time, day, direction, stop (currency and %), target, outcome, and reason for each trade. Never change a rule partway through to make a marginal trade fit — count it as a loss instead.

Chapter 15 — Psychology

In this chapter: what he means by "psychology" and where he places it; the loop from one unaccepted loss to a blown account; loss acceptance; why the P&L screen stays closed; overtrading and the daily stop; revenge trading and breaks; fear, greed and regret; FOMO; ego and overconfidence; patience; process over outcome; and a bounded closing section on life management, kept tied to trading.

Discipline is the single highest video-count subject in the whole ledger, ahead of every technical topic. Much of it is restatement; what follows is the structure underneath it.

15.1 What he means by psychology, and where he puts it

His definition is consistent across five years: psychology is "the way you think" — how you think, talk to yourself, and act. His diagnostic argument: the market is identical for everyone, so a persistent loss cannot be the market's fault — it has to be a loss of self-control. He organises trading into a "four quadrant" framework (technical, risk management, psychology, life management), all four required before a trader earns anything.

****Where psychology sits in the learning order is the one place his teaching visibly reversed.**** In 2021 he called trading "80% psychology, 20% analysis" and said belief work comes before strategy work. From 2024 he inverts it: he tells students to drop psychology focus and go collect data instead; by June 2025 he calls the "bad psychology" diagnosis false outright — most traders simply lack a technical strategy, and psychology only matters once you have one. This is a genuine dated evolution, not smoothed over — though he kept producing psychology material throughout, suggesting a shift in priority rather than abandonment.

What doesn't change: his account of why *knowing* a rule isn't enough to follow it. All technical knowledge is theory, because you're a different person before and after taking a trade. His 2026 mechanism: under stress, control passes from the logical brain to what he calls the amygdala, and once it becomes survival the brain won't let you stop yourself — offered without going deep into neuroscience, and treated here as his framing, not established fact.

15.2 The loop: how one loss becomes a blown account

His most-repeated structure, drawn the same shape from 2020 to 2026: break the rule, blame yourself, get angry, overtrade, blow the account — loop restarts. The engine is the pain of loss creating an urge to recover it immediately. He puts the tipping point at the third trade: once you take a

third after two stop losses, the fourth and fifth follow automatically until the account is blown. Critically, he insists the same loop runs on the *profit* side — euphoria becomes overconfidence becomes overtrading, and it works for a few trades first, which is exactly what reinforces it. His own history illustrates it: a Dubai session where roughly Rs 60-70 lakh made was given back entirely and closed at minus Rs 10 lakh; a November 2025 three-crore loss he called a combination of luck and his own mistakes.

His explanation for why the loop persists even in traders who can recite the rule: the refusal to book a loss is a survival reflex — thinking that booking it means you can't pay rent.

Editor's note — the loop has a name in the literature Cutting winners early while holding losers, and escalating risk after a loss to reach breakeven, is the *disposition effect*, documented since Shefrin and Statman's 1985 paper and confirmed on retail brokerage data repeatedly since. The escalation half is what gambling research calls *loss chasing*. His journal-derived pattern shows up independently in the data.

15.3 Accepting the loss

Losses cannot be removed, only managed — he answers this directly and says the answer is definitely no. His five-bucket frame (big profit, small profit, breakeven, small loss, big loss) makes the arithmetic legible: the

only bucket to eliminate is the big loss. The most-repeated behavioural rule anywhere on the channel: hold winners, cut losers quickly — stated as the thing traders instinctively invert.

His pre-trade routine: before every trade, assume the stop will hit, calculate the loss, and only then take the trade. Say the loss out loud in currency and keep cutting quantity until it's a number you can accept — a quantity, not a percentage. He splits losses two ways: financial vs. emotional (the emotional one is worse, which is why small stop-outs damage more than their rupee value), and good vs. bad (a good loss wasn't your fault; it's never the market's fault, so review is only about which category).

Editor's note — the loss that could not be booked His claim that an uncut loss keeps growing until unrecoverable, tied to the survival-reflex framing about rent, has a canonical institutional example. Nick Leeson at Barings Bank hid a small mistake in an error account in 1992; every subsequent attempt to trade it flat added to it. By 1995 he was carrying huge Nikkei positions taken specifically to recover the hole; the Kobe earthquake moved the index against him, he doubled rather than booked it, and the £827 million final loss destroyed a 233-year-old bank. Same three steps he draws on a ₹300 retail loss — scale changes what gets destroyed, not the sequence.

One point genuinely conflicts, unreconciled: his dominant position is that exiting from fear before the stop is an error — he calls his own premature exit on one trade "a huge mistake". But in one September 2023 video he

states the opposite: "if you are afraid in a trade you should get out".

Readers should treat take-the-stop as the doctrine and the fear-exit line as an unreconciled exception stated once.

15.4 Not watching the money

One instruction recurs more than almost any other: while a trade is running, do not look at the P&L screen. Stated from 2020 through 2026, where he says he hasn't looked at his own P&L during a live trade in years. His mechanism: unrealised numbers are not real, only raise blood pressure; watching makes you want to exit winners early and unable to cut losers. He calls repeated checking an addiction comparable to drinking or smoking, and is candid it's hard — he once admitted seeing his own P&L by accident.

He treats position size the same way — a psychology problem, not arithmetic. Size must stay inside your *emotional* capacity, not your capital: an affordable-but-unbearable size leaves damage even if the money comes back. He demonstrates it against himself, declining to risk \$40,000 he could afford because at that size his heart would race and he'd cut the trade early.

Editor's note — why the P&L screen specifically An open position's unrealised value gives a second, constantly-moving reference point that competes with the plan's stop and target — the peak unrealised figure becomes an anchor, so a position can be showing a real profit and still feel like a loss. Institutional desks separate execution from position monitoring for exactly this reason. Deleting the trading app entirely removes the notification channel, not just the temptation.

15.5 Overtrading: the count, decided in advance

He calls overtrading the biggest killer in the stock market and makes his strongest unqualified claim: stopping it alone makes you "almost 99% sure of surviving" — his own framing, not measured data.

The trade count must be decided in advance. The number itself varies — his most-stated cap is two trades or two stop losses a day, but he's also given three, one for beginners, and one-or-two-or-three "as you decide". The specific number matters less to him than that it's pre-committed and unbroken. A break-even or trailed exit doesn't count toward the total.

The day also ends on a win, not just two losses — no trailing, no sizing up, no further trades regardless of mood. Fewer setups is the structural fix: cutting from seven-or-eight setups to three-or-four is what he credits with turning his own equity curve upward.

Enforcement is physical, not willpower. He walks through the broker's kill switch, which blocks his own trading for twelve hours once confirmed, and uses it himself after two stop losses. He calls it only a "temporary fix" while still telling viewers to use it — and once, flatly, said there is "no cure" for overtrading, a line that sits against the whole battery of remedies.

Editor's note — what the evidence actually looks like in his market

His "99% survival" figure has no data behind it, but there is public data on his own audience's market. India's SEBI published studies (Jan 2023, and a follow-up covering FY22-24) finding roughly nine in ten individual equity-derivatives traders lost money, with transaction costs consuming a substantial share of loss-makers' turnover — matching his own point that not overtrading both makes money and keeps brokerage down. The data supports his direction (higher activity correlates with worse outcomes) but not his number — a population correlation is not an individual survival rate.

15.6 Revenge trading, the day-stop, and taking a break

He defines it by motive, not mechanics: re-entering to recover a loss, and reframes it sharply — it's not revenge on the market, it's revenge on your own ego. **The rule:** stop for the day after two stop losses, regardless of setup quality — he won't take even a "god-level" trade after two stops. His

own figure: of 25-30 times he took a third trade anyway, he recovered only once — his own recollection, not a journal count.

Enforcement again is physical: turn off the laptop and phone and leave the house. His 2026 version is stronger — force yourself into deep meditation immediately, timed to the moment the survival reflex is strongest. The next day is declared fresh, not a continuation; recovering yesterday's loss is not today's job.

For a sustained losing period he prescribes real time off — his most structured version is a two-week restart: week one is a total detox (delete every trading app, don't look at the market at all) because you can't move from negative to positive directly, only negative to neutral to positive; week two is the account review, deferred because looking too early makes you cry over it rather than learn from it.

A real, unreconciled tension. Against all of the above he also says never stop trading during a losing run — but attaches an explicit precondition: only if you've backtested the strategy. The two positions are compatible by condition — break for beginners and untested strategies, trade through for a strategy with real data behind it — but he never states that reconciliation himself.

Editor's note — pauses the person cannot revoke His kill switch and walk-out rule share a design principle: the decision to stop is made calm and executed by a mechanism the agitated version can't override. The same principle runs exchange circuit breakers (built after 1987) and gambling self-exclusion schemes, which block a registrant for a period they cannot shorten once set. A pause you can cancel at the moment you most want to cancel it is not a control — which is presumably why he calls the kill switch temporary: it stops today's session, nothing stops tomorrow.

15.7 Fear, greed, and regret

He reduces execution error to two emotions dominating the mind. **Fear:** physical (trembling hands, stomach ache), and he traces the failure to hold a *winner* to it too — specifically fear of losing the profit already held. He doesn't claim fear is eliminable — tells a student it "has no answer," and his only remedy is journaling why it came, over a long period; it goes with time, not technique.

Greed he treats as a boundary problem: the target must be booked even when greed says go for more. His recurring analogy — you don't drink the whole ocean, only your thirst's worth. He states a hard sizing consequence: never increase risk per trade as the account grows, decrease it if you're up on the day — "the biggest secret in the industry".

Editor's note — "don't be greedy" vs. "hold your winners" Read alone these look opposed. The boundary is the plan, not the emotion: exiting *short of* the planned target is the fear error, extending *past* it is the greed error. Both are deviations from the same pre-committed line — which is why the target has to be fixed before entry, not judged live.

Regret, including after a win, he treats as unavoidable rather than fixable — sad even when he books a profit, because more would have come had he held. His defence: what he planned is his, the rest belongs to the market. Operational rule: once a trade is finished, close the laptop or switch charts and never look back at that one.

15.8 FOMO and the comparison feed

Missed trades are free, is the core instruction: if the market runs without you, you miss the trade but don't lose money. He makes it a training instruction — the obvious trades will come about ten times a day; miss them on purpose and cultivate no regret. He's candid about the cost: regret is a "slow poison" that makes traders impulsively chase the next session, collecting fresh stop losses.

The comparison feed gets specific instructions: unfollow traders who post profit screenshots — a trader needs information, not motivation. He traces the mechanism from comparison to ruin — seeing large P&L posts pushes

leverage on small capital, which bursts, and the cycle repeats until you isolate from the input.

Editor's note — the comparison feed is a designed product His unfollow instructions treat other people's profit posts as a switchable input, which is right as far as it goes — but the same incentive runs inside trading apps themselves. Robinhood displayed confetti animations on trades for years; Massachusetts regulators cited the game-like design in a December 2020 complaint before it was removed in 2021. His remedy of deleting the app entirely removes the notification channel, not just the temptation.

15.9 Ego and overconfidence

The instruction is to separate trading from identity — if a target makes you feel like god and a loss makes you feel you chose wrong, you're not a trader. He names ego as a sizing failure, not an entry failure: small accounts get breached by big lot size and ego, not wrong entries.

Overconfidence he locates after wins, not before them — his symmetrical streak rule: never sad on four losses in a row, never euphoric on eight targets. The rule he attaches: if a winning streak makes you want to put the whole account into one trade, stop and take a four-to-five-day break — triggered by the urge to size up, not by any loss. He names the illusion of control directly: a trader controls only entry and exit, never the

outcome — "nobody enters at the top and exits at the bottom; anyone claiming to is lying."

15.10 Patience and the law of random distribution

Patience is defined by refusal — he won't trade until his setup appears, even watching a level break and run without him. His honest trade-off: a high-win-rate strategy comes rarely (two-three times a week), which demands patience; a low-win-rate strategy fires often and needs none.

The law of random distribution — his own coinage — is that the order of your next twenty-five trades is unknowable, only the rate; since order can't be managed, size can be. Manage wins and losses by risk-reward ratio. His 2026 formulation: have an edge, trust the law of random distribution, never close the casino.

Editor's note — what this term is and is not Not a standard statistical result — what he's describing is the ordinary consequence of independent trials with a fixed win probability, where the rate is knowable over a large sample while the order stays unpredictable. Two cautions he doesn't state: the reasoning only holds if the win rate is actually *known* — his own precondition, "only if you've backtested," is doing all the work. And trade outcomes aren't fully independent — correlated positions and a trader's own degrading behaviour after losses cluster outcomes in ways a fair-coin model doesn't capture.

15.11 Process over outcome

He judges a day by whether it followed the plan, not by the outcome — trades to follow process, not to make money. **Never change the strategy after losses**: the trade you skip after a losing streak is the one that works; you change your approach and method, not the strategy itself. Judge over a long enough window — at least thirty trades before judging results.

Editor's note — judging the decision, not the result This is the hardest instruction in the chapter to actually follow, because outcome arrives loudly and decision quality doesn't. The behavioural-decision term is *resulting* (Annie Duke) — reading backwards from outcome to judge the choice. Its classic case is Super Bowl XLIX's intercepted goal-line pass, declared the worst call in the sport's history within minutes despite being statistically defensible. One bad outcome doesn't make a bad decision — exactly his point when he says a losing trade "contains no mistake to find" if the confirmation was correct.

He's honest about his own compliance: holds his two-stop-loss rule about 80% of the time, follows his morning routine 60-75%. It took him roughly four years to reach booking profits without emotional turbulence.

15.12 Life management: the fourth quadrant

This is the material most likely to read as generic self-help, and he says himself audiences find it boring. It's kept bounded here, tied only to what he explicitly connects back to trading.

His fourth quadrant is responsibility — nobody else applies the other three for you — built from meditation, the gym, and reading. **Meditation's stated purpose is operational**: so a stop loss being taken doesn't make you angry. His mechanism claim — sitting with an urge without acting on

it is itself what breaks the old pathway — is his own physiological account, not sourced. The simplest version he prescribes is counting backward from 100 to 0, because reversing the count forces focus in a way automatic forward-counting doesn't. Applications tied directly to trading: meditate before opening charts; meditate immediately after a loss, at the moment the survival reflex is strongest; journal right after meditating, while still rational rather than emotional.

Habit formation uses a road metaphor — the path taken most often becomes a highway, the path taken rarely stays a pothole-filled village road. Two methods only: break the old pattern (his tool is meditation), build the new one (his tool is force — go to the gym even when you don't feel like it). His 2026 hardening: "forced discipline" — a lockbox for his own phone, timed shut for four to five hours.

Goals and motivation: setting an absurdly large goal equals having no goal; motivation comes free once a goal has emotional attachment, so the fix for low motivation is a better goal, not more motivation.

Editor's note — where the life-management claims are and are not supported Several factual assertions here carry no source: that only

6% of people meditate while 98% of self-made rich people do, a 60,000-thoughts-a-day figure, the subconscious as "a thousand times more powerful." These should be read as his framing, not findings. The behavioural core — a fixed pre-market routine, a deliberate cooling-off gap between a loss and the next decision, physical removal of the device enabling the impulse — is the same structure trading floors impose on themselves through mandatory position limits and forced holidays, because resolve alone doesn't hold.

What he doesn't say

- **No operational test for the emotional states.** "Fear," "greed," "ego," "FOMO" are

used as everyday words with no in-the-moment test to distinguish a fear-driven exit from a legitimate one.

- **The psychology-first/strategy-first reversal is never addressed as a reversal.**
- ****Break-versus-trade-through during a losing streak is only reconciled by an**

unstated bridge** (the backtesting precondition).

- **No diagnostic for identifying which failure mode is yours** — the journal is the

only instrument offered, and it's covered in [[Ch. 14]], not here.

- **Paper trading is genuinely unresolved:** told to beginners, then said psychology

won't come from it, then told to a specific student not to do it at all.

- **Nothing on the clinical end of the material he raises.** He reports messages from

viewers describing suicidal thoughts after large losses and describes traders in heavy depression. His prescriptions are a detox week, meditation, and a break. He does not suggest professional help.

A note from the editors, not the creator: if trading losses have brought you to thoughts of self-harm or suicide, that is beyond what any trading method, journal, or meditation practice can address, and beyond the scope of this book. In India, the KIRAN mental health helpline (1800-599-0019, toll-free, 24/7) and iCall (9152987821) offer confidential support; readers outside India can find a local crisis line at findahelpline.com. Please reach out.

Chapter summary

- Psychology is "the way you think"; because the market is identical for everyone, a

persistent loss is treated as a self-control problem.

- His position on where psychology sits reversed: 80% of trading in 2021-22, versus

something that only matters once you have a data-tested strategy by 2025.

- The recurring failure structure is a loop — loss, refusal, recovery impulse,

overtrading, blow-up — running identically on the profit side.

- Losses can't be eliminated, only managed; of five outcome buckets, only the big loss

must be removed.

- While a trade runs, the P&L screen stays closed.
- Overtrading gets the hardest attack — a pre-committed trade count, enforced

physically rather than by resolve.

- Fear is exiting short of plan, greed is extending past it — both deviations from the

same pre-committed line.

- His "law of random distribution" — manage size, not order — only applies to a

backtested strategy.

- Life management is quadrant four, prescribed not as wellness but so a stop loss

doesn't provoke anger.

Try this

Fix the count, then remove the option. Before tomorrow's session, write down two numbers: max trades, and stop losses that end the day. He says the count can be one, two or three as you decide, but it must be fixed and unbroken — only actual stop losses count, not break-even exits. Then find the mechanism that makes breaking it impossible — a broker kill switch, or simply shutting the laptop and leaving the house.

Chapter 16 — What He Tells Beginners

In this chapter: the advice he gives to people who have not started yet or have just started — learn before you trade, what to study and ignore, which instruments to avoid, how much money to bring, the errors he names most, and the timelines and returns he says are realistic.

This material is scattered across six years and hundreds of videos rather than collected in one place. What makes it a chapter is that the same instructions recur in the same form regardless of context.

16.1 Learn first, trade later

The most repeated instruction on the channel: a new trader's first job is study, not trading. Asked what advice he has for new traders, he says learn, and diagnoses why they don't — they think they already know a lot because they can draw a trendline. Still stated in 2024 as "a very important advice": learn before putting money in. His mechanism claim: most people take their maximum loss *before* they ever learned anything, and that failure is the avoidable kind. He names the loop — download an app, deposit, lose, take another trade to recover, lose again — and has a term for the method inside it, "guess trading": opening a demat account

and trading on whims, no method at all. He defends the time cost with occupational analogies: learning to trade is like four years of engineering; has anyone seen a doctor operate after fifteen days of study?

Operationally: in his 2021 roadmap, step four is to fund nothing — open the account and paper trade, real funding deferred to step five. Beginners get told not to take a strategy live at all, only observe; a new trader should not take a funded account because they will lose it — demo first. For someone with a few hundred to a lakh hoping to turn it into a crore, his advice is to invest it in yourself instead, starting with books.

Editor's note — what "paper trade first" does and does not buy you Simulated trading reliably transfers platform mechanics and pattern recognition. It does not transfer loss tolerance — he acknowledges this himself elsewhere, noting a demo carries no emotion. Paper trading removes mechanical errors before you pay for them; the emotional curriculum starts only when real money is on the line.

16.2 What to study, and the longer list of what to ignore

He treats most of the curriculum as noise: roughly a thousand topics, nine hundred a waste of time, about a hundred worth studying — a ratio repeated with different round numbers elsewhere, not a counted list. He

starts an outright beginner with the market itself — what NSE/BSE are, how many types of trading exist — and insists study be chronological, since there is only one skill being built.

Most curriculum advice is subtractive. Don't stack indicators — piling them on complicates the chart past usefulness, demonstrated by loading Ichimoku, Bollinger Bands, a moving average and ADX onto one chart until price disappears. Nothing beats candlesticks; skip Heikin Ashi, Renko, Kagi, point-and-figure — he calls them disturbance, having used all of them. Ignore the charting platform's home-page data blocks and bottom panel entirely as a beginner; ninety percent of a platform's tools go unused, and he tells viewers to skip harmonic pattern tools outright.

16.3 One strategy, not fifteen

Don't rote-learn pattern names — read structure instead; a 2026 class tells students to skip evening star, shooting star, hanging man entirely and keep two categories, power and reversal. He calls harmonic patterns garbage meant to confuse and rates ICT bad *for beginners* specifically, as over-complicated.

The positive instruction is singular focus: hold one simple price-action strategy and put all effort into it, rather than believing new strategies will make you money. Stop dancing between head-and-shoulders today, box breakout tomorrow, ICT the next — nothing happens that way. He

diagnoses his own losing streak the same way — fifteen-plus ways of trading price action, not price action itself, as the problem.

He names over-analysis as mistake number one for why traders fail, illustrating a sequence: the simple technical buy is right there, but the trader checks open interest, then VIX, then the US market, and the target is hit and missed by the time they act. If you trade gold, trade gold — don't waste time on the DXY chart. Hardware belongs in the same category: four screens aren't required to trade; technicals, risk management, psychology, plan and lifestyle come first, and an elaborate rig helps nobody who hasn't built those.

Editor's note — the over-analysis trap has a name The mechanism he doesn't name is overfitting: each added filter both reduces the number of trades your method produces and increases the chance its historical usefulness was coincidence — requiring four filters to agree doesn't multiply independent edges, it mostly shrinks your sample until you can't tell if you have one at all.

16.4 What he tells beginners not to trade yet

Options top the list: if you're watching a video on how to start, options are not for you, stay away — it's the most expert-level instrument, and everything is learned beginner, then intermediate, then advanced. When

beginners do buy options, he pushes in-the-money strikes consistently: an ITM buyer still has a chance of managing the position, OTM is very risky and can disturb the whole account; on expiry day, go deep ITM. Being right on direction and still losing is usually wrong strike selection. With only Rs 10,000–20,000, don't trade options yet — save more first.

Beyond options: avoid gold completely as a beginner; crypto beginners should hold Bitcoin only, not even Ethereum, while he trades both himself; futures swing trading is absolutely not for beginners with small capital; stay away from penny and operator stocks; skip binary and gambling-type products.

Editor's note — why "in the money" is the safer beginner strike

The mechanism is delta. An ITM option's price moves something like 60-90 paise per rupee the underlying moves; a far OTM option might move five paise and decays toward zero regardless of direction — implicitly betting on a large *and fast* move. Far-OTM weekly index options routinely expire worthless the same afternoon they're bought.

Scalping is the style he warns off most consistently: he calls himself a risk-reward intraday trader, not a scalper, found scalping hectic with no peace of mind, and says beginners in particular should not do it. The one-minute timeframe is "extremely unreliable" and has ruined people because it looks easy. His prescription is the fifteen-minute chart: learn to drive in a Wagon R, not a Ferrari.

Beginners should watch the first fifteen minutes rather than trade them, coming in around 10:00-10:30 instead — and if nothing is there, do nothing and leave. Stay away from scheduled economic events, since that's when very large candles print and handling them takes time to learn. And finally: don't copy him — his capital and risk appetite differ. For beginners he prescribes set-and-forget — plan the trade once, set it, forget it — because a beginner hasn't seen enough to judge developing conditions. Divide his numbers by three; you won't be able to replicate them. He can risk Rs 10,000 on a trade because he has more than a crore behind it — the confidence comes from the capital.

16.5 How much money to start with

The framing is constant even as the numbers move: money brought as a beginner is tuition, and nobody expects to double their tuition fees — the label kills the urge to double the account by Monday. The figures themselves range widely across years: Rs 10,000 with nobody earning from that capital in 2020; \$250-1,000 for a first crypto account in 2021; explicit disagreement with sub-Rs-5,000 advice in 2023; never more than Rs 10,000-25,000 for equity beginners in 2026. His 2026 general principle reconciles most of it: don't deposit so little you wouldn't accept the loss, nor so much it scares you.

What's consistent underneath is the direction of the error he's guarding against: the problem starts when you try to make a big profit from a small amount of capital — earn only what the capital allows, and let more

capital come later. Low- capital option trading of Rs 200-500 won't make you a crorepati — use it to understand the market first.

Undercapitalisation is a mechanical trap too: a trader down to Rs 3,000 can't afford one lot and is pushed into OTM options, while a Rs 18,000 trader can still take ITM.

Two hard prohibitions: taking other people's money to trade is very risky for a new trader, who shouldn't do it; and never take money from others while you're in loss — a rule attached to people whose families and friends turned on them.

Editor's note — why the "tuition fee" label is doing real work This is mental accounting: money labelled as a fee for a service is psychologically pre-spent, so its loss doesn't trigger the recovery reflex a loss on "investment" money does. The catch is the label only works applied *before* the deposit; relabelling a loss as tuition after it happens is rationalisation, not risk control.

16.6 Trading without a stop loss, and averaging down

He treats no-stop-loss trading and no-sizing-method as the two core problems that define gambling versus trading, ahead of everything else. In a 2024 course he names no-stop-loss trading as the first reason accounts are lost — an event you didn't see coming, a big candle against the

position, career over. He specifies for beginners a touch-basis stop, closing-basis reserved for the experienced, and describes the specific escalation: two stop-outs followed by a winner, so the trader skips the stop on the third trade and takes a very large loss. His diagnosis is memory-weighted — traders remember the one time the market reversed right after their stop and ignore the four times it didn't. His own largest disclosed loss was a Bitcoin long held with no stop, on the assumption it could only dip so far, depositing more as it fell.

Editor's note — "touch basis" versus "closing basis" A touch-basis stop executes the instant price trades through the level; a closing-basis stop waits for the candle to close beyond it. Closing-basis survives stop-hunting wicks but exposes you to an unbounded gap; touch-basis caps the loss but pays for it in premature exits — a standing order the broker executes whether or not you're watching, the discipline he says beginners don't yet have.

Averaging down. His second plan rule is never add to a trade already in loss — it becomes a habit and it's a losing strategy. He supplies the psychological mechanism from the options side: an OTM option often prints red the moment you buy it, breaking morale so badly the trader adds money to it instead of accepting the loss. He catches himself doing it once — reviewing his own order book, finds an entry followed by more quantity at a lower price, names it negative averaging, says he'll never do it again.

Sizing by feel. Quantity must come from a calculation, not from picking a number that comes to mind. He teaches this as a mistake he made himself, having used his entire capital on early-career trades. The leverage accident: you meant to take 0.1 lot, you type 1, the platform simply accepts it — at quoted leverage up to 2,000x, a small move against you ends the account. One correction he repeats because he expects the misreading: a risk percentage applies to the size of the stop loss, not to the capital deployed — on a Rs 1 lakh account, 5% means a Rs 5,000 stop, not a Rs 5,000 trade.

16.7 Revenge, overtrading, and entering at the wrong moment

He names revenge trading the single biggest mistake — doubling lot size after a loss and taking a still bigger loss. The cascade: lose in one stock, get angry, overtrade into Nifty, Bank Nifty and back into the same stock. Raising risk after a loss is the common mistake; new traders feel ashamed of losses and then ruin everything trying to recover.

The standing entry mistake is buying late, at the breakout, when the market is already moving — never take a trade directly on the breakout, wait for the pullback; 65% of breakouts fail. His two named entry problems are symmetrical: early entry before the candle closes, tied to FOMO, and late entry, waiting past the close and getting in after the move has grown. His corrective is deliberate abstention — the obvious trades

anyone can take come about ten times a day, and you have to miss them on purpose.

The corrective for all of this is written self-review: after a loss, name the failure points explicitly rather than feel them. The first output of a post-mortem is a written list of your own bad habits, answered from account data, worst one marked in black pen. His bonus rule, the shortest in the chapter: if you make a mistake, don't make it again.

16.8 What is realistic: timelines and returns

Time. Figures cluster loosely around one to two years but aren't consistent: six months to a year and a half in 2020; roughly two years even after learning in another 2020 video; at least one to two years in 2025, specified for someone working alone. His most honest version declines a single number — some six months, some a year, some four or five years.

Returns. To beginners specifically: don't expect returns at all, survive, stay at break-even; if you merely break even as a beginner, that's already a thank-God outcome. Asked for a beginner's goal, he gives 5-10% monthly; elsewhere, 5%, 10% or 15% "would be very good," period unstated. He repeatedly refuses to answer the income question at all — it depends on the system, the risk-reward ratio, the stop loss, not the capital

size; don't forecast your own earnings, because expecting too much and missing it feels very bad.

Win rates. Unusually consistent: no strategy in the world gives 100%; his own setups get 70% easily but he plans assuming 50%, because the math still works. For a single price-action strategy backtested over two years, expect 55-68%, not more. His evidence for the claim/reality gap: about 90% of giveaway applicants claimed a 90% win rate, and strategies claiming 80% on two months of data didn't reach 40% on inspection. Two to five screenshots is not data — a strategy needs backtested history.

The loss statistic. He uses the industry's 90%-fail figure inconsistently — the clearest tension in his beginner material. He states it as fact repeatedly, but in a dedicated 2022 video rejects it: the claim depends entirely on the definition of "trader" — count anyone who can operate a demat account and press buttons on tips, and of course it's 90%+; his own subscriber-poll data rounds closer to 50:50. He never reconciles the two positions — using the high figure when warning, the low figure when defending the profession.

Editor's note — what the regulator's own data says SEBI's January 2023 study of individual equity-derivatives traders found around 89% lost money in FY2022. This backs his high figure specifically for *derivatives* traders, while his definitional objection (that these studies count everyone with a trade in the segment, including one-off punters) has real force too. Neither the data nor this reading is his.

16.9 The recurring temptations, and content he tells beginners to distrust

Everyone plans to hit one home-run trade and quit, and nobody who tries actually quits. Getting rich in a week is simply impossible — out of millions only a few get lucky, so don't chase luck. There is no fast money in the market, only slow money, and slow money is what stays with you. His standing metaphor is cricket: come to play a test match, not a T20 — you can't hit six sixes over and over, not even Kohli or Dhoni.

He also warns about early success specifically: a beginner meets beginner's luck, makes some early profit, and that is the trap, not the reward — linked to emails from people who took loans on the strength of it and can't repay.

Editor's note — beginner's luck is not luck, it is sample size A small number of trades can't distinguish skill from noise. If a method wins half the time, roughly one new trader in four will win their first two trades purely by arithmetic, no edge required — judging whether a method works needs dozens of trades, not three.

He tells viewers to unfollow accounts running fake motivation — ten thousand into a lakh, hero-to-zero — because that path ends at zero and then negative. His standard for choosing a teacher is whether you're learning skills, not watching profits — someone showing ten crore hasn't given you one rupee, and he applies the test to his own channel too.

Specific claims about what the numbers hide: the huge percentage returns posted are often calculated on leveraged value; the "I dropped out of college and became a crorepati" story is a complete lie with no relation to success. His procedural test: demand a verified statement link, as he publishes his own — people showing high-risk profits will never give you one.

Editor's note — a verified statement raises the bar, but does not

clear it Third-party track-record services verify trades happened on a real account; they don't verify it's the person's only account, or that the strategy is survivable. A martingale account (doubling size after every loss) produces a near-perfectly smooth verified curve for months, then loses everything in a day. Read the maximum drawdown, not the headline return.

What he doesn't say about this

- **No single, stable starting-capital figure.** The range runs from \$250 to Rs 25,000,

with some videos advising not to fund at all — he never states a rule that generates the right number for a given reader.

- **He does not reconcile the loss statistic** — asserting and debunking the 90% figure

without saying which version supersedes.

- **He rarely states the period for his return figures** — "10%,"
"5-15%" appear without

a clearly stated timeframe and shouldn't be read as monthly unless he says so.

- **No test for when a reader has stopped being a beginner**, despite
nearly every rule

in this chapter being scoped to that boundary.

- **He doesn't give the stop-placement method** in the video where he
says placement is

the problem, nor the sizing calculation where he says quantity must come from one — both deferred to other material.

- **His curriculum exclusions are stated as judgements, not tested claims** — the

dismissal of harmonics and most candle patterns is asserted without the backtest evidence he demands of others.

Chapter summary

- The most repeated instruction is to study before trading, with funding deferred and

observation substituted meanwhile.

- Curriculum advice is mostly subtractive: one strategy, minimal indicators, minimal

pattern vocabulary, no hardware until fundamentals are in place.

- Options, gold, crypto beyond Bitcoin, futures swing trading, penny stocks and scalping

are all off-limits for now.

- Bring money labelled as tuition — small enough to lose, large enough to take seriously

— never borrowed, never someone else's while in loss.

- The two errors defining gambling versus trading: no stop loss, no sizing method.
- Realistic expectations: one to two years to competence, break-even as a good beginner

outcome, a planning win rate near 50%, no strategy at 100%.

- Judge a teacher by whether you're learning a skill, not by the profits on display — a

test he applies to his own channel too.

Try this

Write your own mistake list from account data, not memory. List your bad habits — early entry, early exit, FOMO entry, overtrading, revenge trading, poor technicals, poor risk management, poor psychology — then answer from the data which single habit lost the most money, and mark it in black pen. If you make that mistake again, that's the one instruction to keep.

Chapter 17 — Scams, Brokers, and Self-Protection

In this chapter: the tip-and-signal business as he describes it from the inside; impersonation and the influencer layer around his own name; his rules against handing anyone your money, credentials or account; what a broker actually is; his selection checklist; his regulatory position — including the one part he presents as legal reasoning and is not qualified to give; and the account-level habits he uses to limit what any single failure can cost him.

A note on naming: no broker, platform, exchange operator, funding company or payment service is named anywhere in this chapter — a large share of the source videos carried commercial arrangements, disclosed and discussed in 17.2, so what survives here is the reasoning, never the brand. Regulators, statutes and public exchanges are named where the teaching depends on them. Funded-account material has its own chapter ([Ch. 12]) and is not repeated here.

17.1 The tip-seller machine

He tells this against himself first. As a beginner he handed a tip provider his login to an account holding lakhs, before he knew how to place an

order himself; one lakh became three on the first call, after which he paid over half the profit across and kept following — and labels the whole thing a scam that happened to him. He reports two more of his own accounts wiped by Telegram tip-call operators in 2017-18.

The mechanism he describes is arithmetic, not incompetence: the standard funnel recruits a hundred people, tells fifty to buy calls and fifty to buy puts, discards the losing half, halves the survivors again next call, and restarts with a fresh hundred when the pool runs out. The "no fee, just take fifty percent of profit" hook guarantees payouts for some fraction of clients regardless of skill; advertised accuracy rates exist only for show.

Editor's note — why the funnel needs no forecasting ability at all

This is a known confidence trick — the tout-sheet mailing scam, where a tipster posts opposite predictions to two halves of a list and only ever contacts the half that was right, prosecuted in the US as mail fraud since the 1980s. It's why the accuracy claim is untestable from the customer's seat, not merely exaggerated.

His verification instruction: ask a tip provider for the actual SEBI registration number and check it with SEBI directly, not a website claim; "registration is in process" is a confession the service is selling tips while unregistered. His narrow carve-out — if you're going to take advice from anyone, take it only from SEBI-registered people, for investing, never for trading tips. Elsewhere the rule is absolute: don't follow tips, create your own signal.

Editor's note — what "SEBI registered" can and cannot mean

SEBI runs two separate registrations for anyone telling the public what to buy: a Research Analyst publishes recommendations broadly; an Investment Adviser gives personalised advice under a fiduciary standard. Neither licenses anyone to trade your account or hold your money.

17.2 Impersonation, influencers, and the disclosure problem

Fake accounts use his name to collect money; he says he never asks anyone for money and genuine information comes only from the verified channel. By 2023 he reports many fake Telegram channels running in the academy's name, one with 3.75 lakh subscribers, selling paid index calls — and warns the losses will be blamed on him. His test: his only paid offering is a regulated research service signed up for on the website with PAN and Aadhaar; anyone else selling in his name is not him.

The wider influencer layer gets the same treatment: don't follow people who don't trade themselves and post only to sell something. He calls dropout-success advertising fake and tells viewers to unfollow immediately, granting maybe one in a thousand succeeds that way. "Five thousand rupees turned into lakhs" content, he states flatly, is false.

The actual test he asks viewers to apply is a verified statement: people showing profits from that kind of trading will never share a verified account link, and he invites viewers to name anyone who does. He publishes his own third-party verified statement so his stop-losses are checkable, not just his winners — arguing traders using very high quantity can't publish a link because the eventual loss would be too big to show.

The most useful thing he says here is about himself: any creator handing you a broker or prop-firm link earns commission on it, including him — a "not sponsored" disclaimer should be read as false. He discloses his own arrangement: roughly 30-35% of the spread on every trade his referred clients place, win or lose. He says brokers have offered him 40-50% of referred clients' *losses* and he refused, not wanting revenue that comes from client losses; his policy is to only recommend a broker he personally uses.

Editor's note — how to use a disclosure like that His distinction matters: introducing-broker programmes pay either a share of spread scaling with client *volume*, or revenue share on client *losses*, scaling with the client being wrong. Regulators have moved most directly against the second — the EU's 2018 CFD intervention measures and the UK FCA's subsequent rules targeted exactly this incentive. Neither structure is neutral; a volume share still rewards overtrading. Treat his figure as a floor for what to ask any recommender, not a clean bill of health.

17.3 Never hand over the money, the login, or the account

One rule underneath the specific scams, repeated in several forms: stay away from anyone asking for your money with a promise to double it — they double it, then take it to zero. Get-rich-quick schemes never work.

For algo trading specifically he supplies a script rather than a prohibition: never hand your money over — the algorithm runs inside your own account, and the operator takes a fee or a share instead of the capital. Nobody hands you a successful algorithm free or cheap; there's no such thing as money doubled in twenty-one days. He rejects binary trading and colour trading outright as outright fraud dressed up as trading.

The rule runs the other direction too: never take money from other people while you're in loss — many have been ruined that way, families and friends turned on them. Don't borrow to fund a trade, don't sell family property papers to fund it, and rate trading with borrowed money as very bad on psychological grounds — the pressure increases.

Editor's note — the custody principle underneath all of this Every instruction here reduces to one idea he never names: keep custody separate from discretion. Someone may be given authority to decide, or given your money, but not both — the second converts a bad manager into an unrecoverable loss, which is what made Madoff's operation possible, since his firm was its own custodian. His script — run it in my account, take a fee — is the retail-scale fix.

17.4 What a broker is, and the two business models

In India, the exchange builds the system and broking companies connect to it; the broker only earns brokerage while trading happens between people. SEBI oversees the exchange-broker-trader chain so no fraud occurs; the consequence he draws is that fraud risk is much lower in Indian stock trading than in forex, which has no equivalent.

Offshore, the distinction is structural and it's the heart of his broker teaching. He splits forex brokers into dealing-desk and ECN/STP: an STP broker passes your order straight through to a liquidity provider regardless of size, earns only commission or spread, and doesn't care whether you win or lose. A dealing-desk broker takes the counter-trade against you — your profit is its loss, a conflict of interest. The economics of why small firms end up on the other side (B-book): they lack capital to hedge large flow, so they take it themselves on the assumption most clients lose — making a profitable client bad for revenue. His rule: make sure your broker is STP.

He then honestly undercuts his own rule — almost every company claims ECN today and the claim alone tells you nothing; a broker can claim ECN status by routing to a "liquidity provider" that's really its own company under another name. He's careful with the accusation — not saying a dealing-desk broker will do something wrong, only that the conflict exists.

Editor's note — why the B-book model exists, and what the public numbers show Internalising client flow isn't inherently predatory — a broker whose clients are net long and net short in similar amounts can match them internally and hedge only the residual. The problem is a firm too small to hedge the residual: its revenue then depends on clients losing. Since 2018, European and UK rules require CFD providers to disclose what percentage of retail accounts lose money — the disclosed figures cluster 70-80% across firms and years, the audited version of the ninety-percent assumption he attributes to small brokers.

17.5 The selection checklist

His summary criterion has been stable for years, and it is not price: the most important thing is that your money is safe and withdrawals actually come out. He picks his own broker on safety and long history over lowest cost, given deposits running into millions. Chasing cheap pips, discounts or more leverage is what causes large losses. For offshore accounts the asymmetry is stark: an Indian broker can be complained about to SEBI; an offshore forex broker has nobody to complain to.

Four positive criteria: **size and age** — a branded, long-established, global company rather than a local outfit or a friend's recommendation; **withdrawals** — instant, with any hold above roughly \$1,000 for a day or two a reason to leave; **reliability** — orders fill, deposits/withdrawals

work, support answers, platforms don't freeze on expiry; **costs, last** — spread matters but he's declined brokers with wide spreads despite heavy marketing, and above \$500 he prefers a zero-spread, commission account.

His personal vetting procedure is the most transferable habit here: he doesn't accept a platform's claims until he's personally opened an account, taken a live trade, booked a profit, booked a loss, and tested that withdrawal actually works; he doesn't move full capital across for roughly two weeks.

Negative signals are specific: small brokers phone you, offer extra leverage and deposit bonuses, and behave well while you're losing. The sharpest observation is timing — with cheap or small brokers, trouble starts once you become profitable: stop-losses get skipped, an "event" gets blamed, targets don't get booked.

Leverage sits inside broker selection, and his ceiling has clearly moved: never beyond 500x in January 2021, down to never above 1:200 by June 2025. His structural argument is unchanged: real liquidity providers give very little leverage; brokers inflate it because they want the trader to lose.

Editor's note — the checklist is a solvency test, not an execution

test Read together, his criteria are almost entirely about counterparty risk — can this firm pay me — and spread, the one execution metric, is ranked last. That ordering makes sense for the offshore case: no compensation scheme stands behind the account, unlike jurisdictions with statutory client-money segregation and investor-compensation schemes, where a broker failure is a recovery problem rather than a total loss. He's describing what's left when the safety net is absent.

17.6 Regulatory literacy — and the limits of his

Three regulated layers: Indian equity/derivatives under SEBI; crypto through FIU-registered brokers; and forex — gold, oil, EURUSD — not regulated by anyone in India, a grey area he says only someone with prior experience should enter.

Editor's note — four bodies, four different jobs He uses SEBI, RBI, FEMA and "FIU-registered" as if they described one surface. SEBI licenses exchanges, brokers, advisers; the RBI is the authority on foreign exchange — the alert list of unauthorised forex platforms he reads from is an RBI list, not SEBI's; FEMA (1999) is a statute governing cross-border transactions. The Financial Intelligence Unit is the anti-money-laundering agency; "FIU-registered" is real and checkable, but not a prudential licence, and says nothing about whether the platform can pay you.

His statements on forex legality are unambiguous: forex trading is banned in India and doing it is totally illegal; an Indian resident must never transact directly with a real forex company, since depositing into or taking a payout from one is a dealing under FEMA. He says this is why he relocated to Dubai, and above roughly five to ten lakh of trading capital tells viewers to stop using workarounds and become a Dubai resident with a proper legal entity.

And then, alongside that, he teaches a payment workaround he characterises as legal: offshore brokers keep Indian bank accounts under consultancy businesses, or settle via person-to-person transfers between savings accounts, so the trader never technically transacts with a forex company. His criterion: a transfer between two individuals' Indian accounts is fine; a transfer into a forex company's account makes you liable. His preferred route for small capital is USDT through a third-party exchange, so the broker's banking channel is never touched.

He has the receipts against his own advice. His account was locked under FEMA for dealing with a forex company, with jail a possible consequence; a bank account frozen after depositing into a genuine overseas forex company; another account closed and still not reopenable. The workaround isn't risk-free either — heavy P2P volume triggers bank queries and freezes, by his own unsourced estimate of one or two in a hundred. He concedes the whole arrangement lasts only until the broker at the other end commits a large fraud.

Editor's note — read this section as reportage, not as guidance

This is the one place in the book where the creator gives what is, in substance, legal advice, and it needs a boundary drawn loudly around it. His P2P reasoning cites no ruling, no order, no professional qualification, and is offered in the same breath as a commercial recommendation. The doctrine of structuring — arranging a transaction through intermediaries so the prohibited leg doesn't appear on paper — is generally treated as evasion rather than compliance across financial-regulatory regimes. His own reported experience — multiple frozen or closed bank accounts, a FEMA lock he says could carry a custodial consequence — is the strongest available evidence against relying on any of it. Anyone in this position needs a qualified professional in their own jurisdiction, not a video and not this book.

17.7 Protecting the account itself

He does not keep his whole trading capital at the broker — some sits in his bank account, some in a different demat account, the trading account funded only when needed, as risk- of-ruin management rather than a trade rule. The same mechanism doubles as a sizing control: of one lakh meant for trading, move 70,000 straight back to the bank and trade only within the 30,000.

Two broker-side features he uses as self-binding devices: the kill switch — profile, console, account, then the segment to disable — which blocks his own trading for twelve hours once confirmed; and, to enforce stopping after a booked target, deactivating the derivatives segment, which can't be reactivated for twelve hours.

The stop-loss argument reappears here in its account-protection form: it must be a system stop sitting with the broker, not one held in your head — he says a system stop saved him on a fast event-driven move in gold, and cutting manually would have blown the account. A single huge candle with no stop would break the account.

Three practical consequences of the broker you picked. First, the price feed is the broker's, not the market's — he saw roughly a hundred points of difference on the same instrument between two platforms open side by side, so set the stop against the chart of the platform you're actually trading, not a different charting site. Second, the execution app is not the custodian — money sits with the broker, the platform only reflects the

balance. Third, check which account you're in — real or demo — before anything else.

Editor's note — why the same instrument has more than one price

This isn't a defect or evidence of manipulation — it follows from market structure. Spot forex, spot gold and CFDs have no central book at all: each broker publishes a quote aggregated from whichever liquidity providers it connects to, so two brokers legitimately show different highs and lows for the same candle — which is also why a stop-hunt complaint is so hard to adjudicate from outside.

What he doesn't say about this

- ****He never resolves the tension between "forex is illegal in India" and continuing to**

teach it to an Indian audience.** Both positions are stated as certainties, never as being in tension, with no statement of which a viewer should act on.

- **The P2P legal argument is unsupported** — no regulation, order or ruling cited, no

professional qualification offered, and he doesn't address what the person on the other side of a P2P transfer is exposed to.

- **He gives no test for whether a broker really is A-book** beyond reputational proxies

— size, age, footprint, payout history — none of which reads the actual order routing.

- **The advice to open an account in a relative's name is given with no caveats** — no

legal, tax, KYC or employer-rule qualification, sitting oddly beside his own repeated rule never to share credentials.

- **He does not say what to do once you have been defrauded** — no complaint procedure,

no regulator to approach, no recovery step, beyond noting offshore has nobody to complain to.

- **The leverage ceiling moved (500x to 1:200) and the change is never acknowledged.**
- **Nothing on tax** beyond noting Indian trading carries STT and GST and that a

chartered accountant should be consulted for crypto.

Chapter summary

- The tip funnel needs no skill: split clients into opposite calls, keep the winners, and

the "no fee, just a profit share" hook is the trap. Verify any provider's SEBI registration directly with SEBI.

- Judge a source by the skill you gain, not the profits displayed; demand a verified

statement, and assume anyone handing you a broker link is paid.

- Never hand over capital or credentials — run an algorithm inside your own account for a

fee, never give the money away; never take other people's money while in loss.

- Two broker models: STP passes orders to a liquidity provider and earns the same either

way; dealing-desk takes the other side, so your profit is its loss — but the label can be faked, so treat it as a starting question, not proof.

- Choose brokers on money safety and withdrawal speed, not cost; vet by using — open, trade, book a loss, test a withdrawal — before

trusting a platform.

- Forex is illegal for Indian residents by his own repeated statement, and he separately

teaches a payment workaround he is not qualified to certify — his own frozen bank accounts are the strongest evidence against relying on it.

- Fund the trading account only as needed, keep the rest elsewhere, use the broker's

segment-lock to stop yourself, and always place the stop with the broker, never in your head.

Try this

Run his verification call. Take any tip service or signal channel in front of you and ask for the actual SEBI registration number, then verify it with SEBI directly. "Registration in process" is a confession. Then apply his second filter: list what skills you've actually learned there against what profits you've been shown, and ask for a verified statement covering losses as well as wins.

Chapter 18 — News, Macro, and Fundamental Context

In this chapter: the one principle he takes from Dow theory and repeats more than almost anything else — the market discounts the news before it arrives — how a scheduled result actually moves a stock, how he filters an event calendar, the postures he takes around a release, his budget-day plan, his shifting relationship with global macro, and the boundary between fundamental analysis (investing) and technical analysis (trading).

18.1 The one principle: the market discounts the news

Almost everything he teaches about news rests on one borrowed idea, stated as the first point of Dow theory: whatever price the market quotes at any moment already reflects the information available at that time. He treats this as the only usable part of Dow theory and sets the other five points aside. In 2024 he states it in four words — "market always discounts the news" — repeated three times in one clip.

The operative consequence is negative: what matters is the market's reaction, not whether the news is good. Applied to forex, a positive release

can produce a negative breakout and vice versa — direction can't be predicted from the news at all. The standard beginner error: assuming a good result means the stock goes up, when profit booking is what actually starts, because once the news is out there's nothing left to price in. A strong revenue number is not tradeable in itself — a stock topples after good results as often as it soars.

Editor's note — what "discounts the news" corresponds to outside

his vocabulary This is a practitioner's statement of the semi-strong form of the efficient-market hypothesis: public information is already in price, so the tradeable variable is the *surprise* — the gap between what was expected and what arrived — not the level of the number. The clearest illustration is a scheduled Fed rate decision: when futures already imply near-100% probability of an outcome, the decision itself moves rates very little, and what moves the market is the accompanying statement, which wasn't priced. His "reaction matters more than the news" and the professional's "trade the surprise, not the print" are the same observation from different directions.

18.2 The anticipation trade: how a result moves a stock

He gives a four-case grid for how a stock behaves around a result, conditioned on what price did *before* the announcement. Rallied into a good result: profit booking, falls. Rallied into a bad result: heavy selling.

Fallen into a bad result: a new rally begins, not the next day but over the following two to four days. He puts the pattern's reliability at about 80% — his own unbacked estimate. His recurring example is Reliance, which he says always posts good numbers, always rises, and then topples down.

The trade he builds from this is a *pre-event* trade: trade the price action a week or ten days before the event, never on the day of it or after, in a 5- to 15-day window ahead of the announcement. Exit discipline on result day is where he's most prescriptive: rush to take what the trade has given — the pre-result move is over at that point. If the result has already come and the market has gapped up, don't buy it.

There is a real tension in his own material: in 2021 he said he's simply not the kind of trader who trades the results calendar — the trade is taken on the chart; by 2023 it had softened into a preference — an earnings event combined with good price action is when the trade works amazingly, but he'd take the setup without it too. Read across the dates, the honest summary is that the event is a *reason to look*, never a reason to enter on its own.

Editor's note — why "anticipation" is not just a figure of speech

Analysts publish consensus estimates weeks ahead; positioning builds toward them; by the time the print lands, the consensus outcome is already in price — the everyday phrase for this, which he does use, is *sell the rumour, buy the news*. What his framing leaves out is *post-announcement drift* — price continuing in the surprise's direction for weeks afterward, the opposite of the fade he describes.

18.3 Finding the dates: the event calendar and how he filters it

He keeps event homework deliberately small. For the Indian index, do it once a year: write the consolidated dates on your phone or wall — three scheduled events worth remembering: budget day, national elections, monetary policy; a 2024 video adds Nifty-50 heavyweight results and general elections.

For forex and commodities the filtering is the whole technique. He uses a free economic-calendar site (any such site works) and keeps only the highest-impact tier — red, not orange or yellow; filters to the currencies he actually trades, USD alone for gold or Bitcoin; and states the reason plainly — a full calendar gives too much data and stresses you. The output is a physical artefact: he screenshots the filtered week and sets a phone alert an hour or six hours ahead of each entry, so an event never arrives unnoticed. He also checks the holiday calendar before holding anything overnight.

For stock result dates he uses two sources and trusts neither alone — a chart platform's earnings marker and a dedicated results-calendar site — and confirms disagreements elsewhere before planning a trade. Where a reporting *time* isn't published, he checks the historical results page, having found one stock's times scattered across five different hours — the time is neither fixed nor guaranteed.

Editor's note — what an "impact" rating on a calendar actually is

The colour or star rating isn't a measured quantity — calendar sites assign it editorially, based on how much a release has historically moved the currency. It's a rough prior, not a forecast of today's volatility, and says nothing about how far consensus and actual are likely to diverge this time — he describes exactly this asymmetry himself with an RBI decision where the expected number arrived and the market went nowhere. The rating tells you when to be at the screen; it doesn't tell you a move is coming.

18.4 Three postures around a release

Read across the corpus he takes one of three stances around a high-impact release, depending on instrument, year and whether he's already in a position — and the material doesn't fully reconcile them.

Stand aside, his most frequent position and the one he gives beginners: never trade the exact event, since the market chops rather than runs one way. He holds a trade he was already in, tightens the stop, and never buys into the event — doing otherwise ends a career before it starts.

Manage what you already hold: know every week which days carry events so you can manage an open position. If a trade is in profit as an event approaches, trail the stop to breakeven. He warns a stop can still execute some distance from where it was placed on an event candle — he's had a fixed \$150 gold risk become a \$280 loss on a fast candle.

Editor's note — why stops slip on event candles Market makers widen quotes and pull resting size in the seconds around a scheduled release, because they can't know the number either — the visible order book thins to a fraction of normal depth. A stop order becomes a market order at the trigger price and can only fill against whatever liquidity exists, which may be several ticks away. His instruction — assume the fill may be worse than the level, size for that — is right whether or not the reader knows the mechanism.

Trade the event breakout, the posture he teaches least and has used most recently. In 2022 he taught an explicit news-trading method for forex while opening by saying he's personally against news trading. The method: don't read the actual figures at all; mark levels in advance on a four-hour timeframe; if price reaches a level around release time and breaks out, take that as the trade. He claims it works seven or eight times out of ten — his own unverified figure. He's used this posture himself as recently as 2025, buying gold thirty seconds before an event candle closed, calling the trade very risky and admitting he didn't share it with his community because "accounts blow up in situations like that". The honest reading: his public teaching is stand-aside-or-manage, his private practice includes the third posture, and he says so.

18.5 Budget day: the timing plan

The Indian union budget is the one event he plans in full detail, based on his own study of nine budgets from 2015. He claims the day is always either trending or a V-shape (down then up), never up-then-down, favourable eight years out of nine — no data table shown.

The timing rule is what he repeats most: no meaningful momentum before 10-11am, no position before then, no matter which way it goes. He never listens to the speech itself — a positive announcement can send the market down and vice versa, so the chart is what to watch. He caps exposure at 20-30% of capital and plans exactly two trades, no more. The plan extends to a possible BTST trade — *only* if budget day printed a definitive confirmational candle — and an expiry-day trade in the direction of the gap.

On the options overlay, he changed his mind but the underlying rule stayed stable: he'd run a long straddle in 2020-2022, then in 2023 said it wouldn't work that year — because the budget fell too close to the Thursday weekly expiry, leaving no time value to protect the losing leg. He also reports the strategy failing outright in 2024, the most sideways budget day he'd ever seen.

Editor's note — the volatility mechanic behind the straddle

argument The standard name for what he's circling is **implied-volatility crush**: option premiums embed an expected move, that expectation peaks just before a scheduled event, and collapses the moment uncertainty resolves regardless of direction. A long straddle bought into the event is short volatility in disguise — it needs a realised move larger than the priced-in one just to break even, which is why he observes the option *sellers* were the only ones who made money on the 2024 budget.

18.6 Global markets and the retreat from macro

His use of global macro genuinely changes direction across the corpus — from a daily routine input toward something he actively warns against.

The early material is routine-heavy: watching the Dow, checking whether Asian/UK/US markets were positive before a BTST trade, a 2023 morning checklist putting the US market at step one and Singapore Nifty at step two to anticipate the gap. The dollar index gets the most attention: he defines DXY as the dollar against other currencies, treats 100 as the stable level, and gives the technical takeaway — when DXY goes up, the stock market goes down. He says you *can* trade DXY but shouldn't; trade the more liquid pairs instead, using the index for the view.

The countervailing material is just as clear. In 2023, after a Rs 2 lakh loss, his journal entry told himself to ignore the global market and do what the chart says. In 2024, replying to a comment, he said macroeconomics is not what a trader needs — if you sold and the market went up, macro gives you nothing to act on — carving out one exception: for *investing*, macro is fine. In 2026, after crude and gold broke their usual inverse relationship, he gave the strongest version: never trade on correlation between instruments, because fundamentals can change and break the connection you assumed.

The defensible reading, supported by his own framing: macro survives as *context and calendar *and is disqualified as signal** — he still checks the Dow and SGX to anticipate a gap, but refuses to let any of it override the chart. Readers should treat the 2025-26 material as his most recent word.

Editor's note — what the dollar index actually measures DXY is a fixed-weight basket dominated by the euro (roughly 58%), with no Asian emerging-market currency in it at all — "the dollar" as DXY measures it is mostly EUR/USD. The dollar-versus-emerging-equities relationship is real in long-run data but unstable over weeks — 2023 saw months of a rising dollar and rising Indian equities coexisting, exactly the instability his later rule against trading correlations is reacting to.

He gives FII flow data the same treatment — useful as a slow bias, useless as a trigger. One day of data tells you nothing; read at least 8-10 days, since it alternates day to day. There's no use looking at DII data at all,

since DIIs always buy (SIP, insurance and bond money must be deployed)
— investor-relevant, not trader-relevant.

18.7 Fundamental analysis: reserved for investing

His split between the two disciplines is a split by *activity*, not a blend. Fundamental analysis is required only for investing, not for trading; technical analysis is what you use intraday, and fundamentals are of no use over a horizon of a few days or weeks. He describes himself as a total technical-analysis guy for whom a company's revenue and order book mean nothing. To new traders specifically: cut out fundamentals entirely, trade on technicals alone. But asked which discipline matters more in general, he compares it to asking which eye is more important — both matter in their own place.

His own investing checklist, walked through on screen: financials first (income, balance sheet, cash flow, in that order); is revenue and EPS increasing; is free cash flow increasing, which he calls very important; PE and price-to-book compared against the sector, not judged alone; and the shareholding pattern (promoter, FII, DII, mutual fund, retail), read for whether each is rising or falling, with a spread across all five called healthy. Where checks conflict, financials outrank the PE ratio.

Editor's note — what his checklist is, in standard terms Read as a screen, it's a fairly orthodox **quality-plus-value** filter: the financial-statement steps are quality factors, the sector-relative PE/PB steps are value factors. One thing his version omits: a normalisation for the business cycle — a cyclical steel producer's PE is lowest at the peak of its earnings cycle, not when it's cheapest, a classic trap in exactly the commodity names he screens.

Two qualifications belong to this split. First, a small, recent, hedged loosening: in January 2026 he said he very rarely looks at fundamentals for a trade, but when a fundamental happens to match the technical, "the job is done" — framed as a filter on top of the technical, not a standalone trigger. Second, the failure mode he names in the other direction: mixing *bad* fundamentals into your trading creates disturbance, and traders who'd followed the technicals instead would have made money on the move. His instruction against news consumption during a session is unusually strict — while in trades, no news channel, no Google search on his stocks, no Telegram, no tips.

For the investing side, fundamentals are necessary but not sufficient: stocks he's invested in are obviously fundamentally strong, but the question is whether they're at the right price technically. Buying a fundamentally strong company at an all-time high gives no benefit. In November 2025 he went further — even in investing, technicals matter more than fundamentals — and demonstrated it by buying a bank right after a fundamentally very negative quarterly result, on the strength of where it sat technically. His entry triggers are sentiment- and level-based

rather than valuation-based: buy when everyone is in fear, sell when everyone is greedy; never buy on hype, always buy on fear.

18.8 War, crisis, and the crash playbook

His largest single macro study is a February 2022 look at war periods on the Dow Jones (which has data from 1897, unlike Indian indices, usable only from about 1980), explicitly framed for investing, not trading. His own read-off figures: a 13% dip at the start of WWI, a 113% high from the low with the war still running; similar patterns for WWII, Korea, Vietnam, the Cuban Missile Crisis, 9/11 and Kargil — all recoveries within the war period, none of the events producing a lasting collapse.

His conclusion is tightly scoped: short-term movements have nothing to do with the market, and long-term positions should be taken on fundamentals in such situations — with the caveat, stated himself, that because he's reading a monthly chart this says nothing about tomorrow, Monday or Tuesday. For an investor: don't panic sell, don't stop regular investments, keep investing more during the fall.

Editor's note — reading his war percentages honestly The index he measures on is reconstituted — he makes this point himself, arguing an index is structurally bullish because its worst constituents get replaced — which is precisely why an index's recovery from a war-period low isn't the same as an individual investor's recovery. And nine or ten episodes across a century is a very small, non-independent sample for a claim about recovery magnitudes. Readers should keep the conclusion and hold the percentages loosely.

The August 2024 crash video applies the same playbook live, with an explicit disclaimer: he's not an economics student or professor, just explaining the picture in layman's language. His instructions: don't sell a long-term investment now, since there's no benefit after the fall has happened; don't touch mutual fund SIPs at all; split what you intend to deploy into four equal chunks, adding one on each further 3-4% fall, because nobody knows where the reversal is. Note that in the same video he tells *traders* to position as sellers — the buy-in-fear rule is scoped to the investment book, not the trading book.

What he doesn't say about this

- **He never reconciles the three event postures** — stand aside, manage what you hold,

and trade the breakout all appear as taught positions, sometimes in the same year across different instruments, with no stated rule for which governs when they conflict.

- **The 80% and 70-80% hit-rate figures are unbacked** — his own estimates, no data

shown for either, and the same is true of the budget-day study: nine budgets, no table, no trade log.

- **No position sizing for the pre-result swing trade** — he gives the entry window and

exit cue but no stop-loss rule or invalidation for it specifically.

- **No threshold for "already priced in."** The whole anticipation framework depends on

identifying that a stock "has already rallied into the result," but he gives no percentage or reference level for when a run-up counts.

- **Macro is left unresolved** — from a daily global checklist to "macroeconomics is not

what a trader needs" to "never trade on correlation," without a stated reconciliation beyond carving out investing as the exception.

Chapter summary

- The one principle: the market discounts the news, so what matters is the reaction, not

the number.

- The tradeable move happens *before* the announcement — trade the price action 5-15

days ahead and take what's given on result day itself.

- Keep a filtered calendar, not a full one — highest-impact tier only, only the

currencies you trade.

- Around the event his default is not to enter: never buy into it, tighten or trail the

stop on what's already open, and expect a worse fill than placed.

- Budget day gets a full written plan — nothing before 10:30-11:00, 20-30% of capital at

most, two trades maximum.

- Macro survives as calendar and context, not as signal — he still checks the Dow and

SGX for the gap, but says macroeconomics is not what a trader needs.

- Fundamental analysis is for investing, technical for trading — with a hedged 2026

loosening: when a fundamental matches the technical, the job is done.

- Even on the investing side, price placement outranks fundamentals — a strong company

at an all-time high gives no benefit.

Try this

Build his filtered event calendar, once, for the market you trade. Write the year's index events on one page — for India, budget day, elections, monetary policy. Open a free economic-calendar site, keep only the highest-impact tier, and filter to the currency you trade. Screenshot the filtered week and set an alert ahead of each entry. Then check your last two months of losing trades against the calendar you built — his own diagnostic question is whether the losses cluster around an FOMC, an inflation print or a GDP date. The exercise produces no trade — the point is knowing which days carry events, so you can manage what's already open.

Chapter 19 — Worked Examples

In this chapter: a small set of end-to-end trade walkthroughs from his own recaps and live sessions — a stock short with every number stated, a gold pattern trade, a stock-selection session, a trade that was all management and no entry, a multi-timeframe setup that paid nothing, a losing week and its recovery — each read against the rules established in [[Ch. 5-11]]. Nothing here is new doctrine. It's the doctrine happening, with the friction included.

19.1 How to read a recap of his

Two things need saying first. He presents his own results as a mixed record, unprompted: he opens one video by saying that day's Indian stock trades all hit their stop losses, mentioning the winning crude and gold trades only afterward; opens a weekly review by saying the week started well and became challenging toward the end, including a stopped-out live-stream trade; and in 2020 admits he hadn't become a millionaire trader and earned lakhs, not tens of lakhs, a month.

Second, a recap is not an audited record, and he doesn't claim it is. Some are screen- shared order history he states is a real account; others are figures spoken from memory with no entry, stop or size attached.

Editor's note — the selection problem, and why it is not solved by

honesty He does report losses alongside wins, repeatedly and unprompted. That's worth something, and rarer in trading education than it should be. It doesn't, however, convert a stream of recaps into evidence about a strategy's expectancy. Which trades get filmed is decided after the fact, or at least after the setup appears — a channel that publishes every loss it happens to record is still not publishing a complete trade log. It's the same distinction auditors draw between a sample and a population: a self-selected sample can be perfectly truthful about each member and still tell you nothing reliable about the whole. Compare a regulated fund factsheet, which must cover every month including the ones nobody wants to show. Read the walkthroughs below as demonstrations of process, which is what he offers them as, not as performance data.

A related caution: several of his recaps state a figure once cleanly and then restate it inconsistently within the same passage. Where that happens below, this chapter uses only the cleanly stated numbers.

19.2 A stock short with every number stated

The most complete single walkthrough in the corpus — every element of Chapters 6, 8 and 9 appears with a number attached — is a short in Apollo Hospitals recapped in a 2023 crash-course video.

There was no event behind the stock — no news, no result. Price arrived at his level and didn't break through directly; it went sideways instead. He shorted the candle, put the stop above the pivot — roughly 23 rupees of risk — with a target 40-43 rupees away, coming in above his 1:1.5 minimum at roughly 1:2. He notes the trade had been posted publicly on YouTube before it was taken.

Every rule from earlier chapters is visible and none is being introduced here: the level came first, entry second (Ch. 6); arrival wasn't the trigger, the sideways reaction was (Ch. 8); the stop sat at the structural invalidation point, the pivot, not a comfort distance (Ch. 9); risk-reward was computed before the trade, not measured after (Ch. 11).

Editor's note — why "no event behind it" is a condition, not an aside He mentions the absence of news as part of the setup description, and it's easy to skim past. In practice it's a filter: a level holds because the resting orders around it are the dominant force at that moment, and a scheduled catalyst is exactly what makes those orders irrelevant. He isn't saying levels stop working during news — he's describing a trade where nothing was competing with the level.

19.3 Gold: the full pattern sequence, twice

Gold is his highest-volume instrument, and two walkthroughs show the same structure of argument at very different levels of vocabulary.

The first is a classical-pattern trade from May 2024: on the small timeframe, the market ended a downtrend with a breakout, made a double bottom, broke the neckline, and was retesting it when he took the long — four conditions in sequence, none doing the work alone. He books it live at \$1,242 once the target hits.

The second is the same shape in smart-money vocabulary: a live gold short from a fair value gap above the 50% line, stop above the zone, paying about \$13,000 at roughly 1:4 because the stop was kept small. A third recap gives a short at volume-profile resistance hitting target directly for 1:4 and \$35,000, account size not stated.

The structural repeat across all of them is the stop: above the zone, below the zone, on the entry candle — always at the point that would falsify the setup, never at a chosen distance (Ch. 9). The 1:4 outcomes are attributed to the stop being small, not the target being ambitious (Ch. 11's causal direction).

Editor's note — why the two vocabularies produce the same trade

Chapter 4 records his repeated claim that the smart-money layer is price action relabelled. These walkthroughs are the claim in practice: a neckline retest and a fair value gap entry with the stop above the zone are both "enter where the level should hold, invalidate where it obviously has not." He isn't endorsing either dictionary — he is using both on the same instrument, months apart, to do the same thing.

19.4 A session walkthrough: choosing the instrument before the trade

Not every worked example is a single position. A February 2023 session shows the step that precedes the setup — which instrument to watch. At 10:25am he runs across banking names and finds IndusInd, ICICI, Axis and SBI all showing momentum while Kotak doesn't; Kotak is dropped on the spot. He later shorts SBI as it breaks the 10:15am low, noting Bank Nifty itself was choppy — the index wasn't the better vehicle. In another sequence, Bank Nifty gave a pullback after breaking support while SBI fell straight down, and the trade went to SBI for that reason.

The rule illustrated belongs to Chapter 8: the breakout of the early-session low or high is the trigger, but the instrument traded is the one moving with least hesitation — the index breaking and pulling back while a constituent falls straight down is the relative-strength argument reduced to a single observable.

19.5 The trade that was all management

He's explicit, in one recap, that a video is worth watching for the management rather than the entry — a Polkadot long from April 2022. The trade went to \$3,500 in profit, came back to \$1,000 negative, and was finally booked at \$6,000, with the stop shifted twice using Fibonacci levels. It also shows the cost side honestly: a position that spends time \$1,000 underwater after being \$3,500 up is one many of his own stated rules elsewhere would have closed.

The counterexamples belong beside it. On a Nifty swing he says that if he hadn't cut the trade he'd have made twelve to fifteen lakh, and booked roughly half instead — presenting the early cut as risk management, not a mistake. On a Bitcoin short he says he personally made less than the published levels would have, because he trailed and cut it live. In a crypto course recap he books 3,300 on 1,000 of risk by holding and trailing instead of taking the planned 2,000.

Editor's note — the same rule, four outcomes Holding through the drawdown produced \$6,000; trailing produced 3.3x instead of 2x; cutting early produced roughly half of a twelve-to-fifteen-lakh move and less than the published levels on a Bitcoin short. He doesn't present these as a scoreboard between two policies, and neither should a reader — they're draws from a distribution, and four draws can't separate two management styles whose difference shows up over hundreds of trades, the same reason a fund manager's single quarter says almost nothing about process. What they jointly establish is that he applies the discretion in both directions and reports the version that cost him money as readily as the one that made it.

19.6 A textbook setup that paid nothing

The most instructive walkthrough is one where the analysis was clean and the outcome was zero. On USDCAD he ran the multi-timeframe sequence from Chapter 6 exactly as taught: the 4-hour showed an uptrend and pullback, the 1-hour made a double top and started falling, and he entered short on the 15-minute after a consolidation. The result: a no-profit, no-loss trade, presented as one of his own recent trades rather than a demonstration.

Nothing in the process was wrong by his own account, and the trade still produced nothing. Against the tendency of every other walkthrough in this

chapter, this establishes that a correctly executed setup has a flat outcome available to it, not only a win and a loss.

19.7 A losing week, and what he did on the Wednesday

The most complete drawdown-and-recovery sequence runs across three days in September 2023 — the arithmetic of Chapter 11 under load. He opens reporting a Monday loss of about 3.5 lakh, later attributing roughly two lakh of it to the first trade alone; the second Monday loss was a short taken into a forming head-and-shoulders that went the other way. Tuesday added a further 1,35,000 loss. On Wednesday he used 8 lakh of capital to buy the 19900 Nifty calls at around 150 and booked around 241, a profit of 2,71,000.

Set against Chapter 11, the striking feature is what did not change: the Wednesday position was a normal-sized deployment at a near-the-money strike, not an enlarged one, and the recovery came from a single ordinary trade rather than a bet scaled to the size of the hole. The pattern recurs at smaller scale: in a live session he takes the same \$4,000 risk three times — two losses, then one winner that more than covered them.

Editor's note — why the constant-risk detail is the whole example

Three attempts at the same \$4,000 is arithmetically unremarkable and behaviourally the hardest thing in the chapter. After two losses, the position size that "feels right" moves in one of two directions — up, to recover, or down, from fear — and both destroy the property that makes fixed fractional risk work at all: that every trade draws from the same distribution. The classic illustration is the martingale bettor: doubling after each loss wins small amounts almost always and ruins the account on the one run of losses long enough to exhaust the bankroll. He doesn't use that language; the recap simply records the same number three times, which is what Chapter 11's rule looks like when nothing goes wrong with the trader.

He's also willing to show the version where recovery doesn't arrive: a TCS trade shown live went from an 8 lakh profit to a 10 lakh loss.

19.8 Where the live version departs from the taught version

Across the recaps, the same handful of deviations recur, always narrated by him rather than caught by anyone else. Collected, they're the most honest thing in the chapter.

Entries taken before the candle closed. In a live session he admits he took an entry three minutes before the candle closed, saying mistakes

happen live and this one happened to him. In another, after exiting a put he flipped long on a momentum move, entering in a hurry before the candle closed; the trade didn't work and he closed it small.

Entries on a different timeframe from the one taught. He teaches a setup on the 5-minute and says he actually entered earlier, on the 1-minute. On a gold trade he missed the cleanest entry at the trap because he was teaching a class at the time, and took the setup later on a lower timeframe.

Sizing changed mid-trade or by mood. He increases quantity mid-trade because he judges he can carry the risk — explicitly to test a concept live on camera after three profitable days, not presented as a standard rule. In the other direction, he trades reduced quantity on a gold trade because his attention was elsewhere, making about \$500 on two lots.

Targets that were not the target. He booked a Bitcoin long at \$9,326 after planning for \$3,000-4,000. Running the other way, on his last two live trades he hadn't reached the full target — roughly 80-90% one time, only 30-40% the next.

Editor's note — reading a deviation list correctly None of these entries is presented by him as a revision of the rule. "I entered three minutes early because it was live" is an admission, not an amendment, and a reader who collects the deviations into a permission structure has inverted the material. The useful reading is the opposite: the rules in Chapters 8 through 11 are stated strictly enough that their author can be seen departing from them on camera, which is more than can be said for advice vague enough never to be violated — the same reason a written pre-flight checklist is auditable and "fly carefully" is not.

What he doesn't say about this

- **He does not publish a full trade log.** The recaps are individually specific and

collectively incomplete; he never presents a period's complete set of trades with entries, stops, sizes and outcomes. The closest he comes is reading a broker statement aloud — a crypto statement of roughly thirty closed trades showing almost as many losses as profits and still a large net gain.

- **He does not state a win rate for any of these methods.** Individual sessions are

counted in handfuls — one target and two stop losses in a walkthrough sequence — but he never aggregates them into a claimed hit rate.

- **He is inconsistent about what counts as a good return, unresolved.**

A 2-2.5% return

on option-selling capital is "not that great"; a roughly 7% day on 5 lakh in equity is "good"; an option-buying leg turning 10 lakh into 14.5 lakh is called "140% in one week". Different instruments and capital bases may explain it, but he never reconciles them, and no single benchmark for "a good return" can be extracted from the recaps.

- **He rarely states account size behind a profit figure.** A \$35,000 gold result is

given without the account it was made on. Without a denominator these figures cannot be turned into a return.

- **The transcript record is noisy in exactly the places that matter.** A substantial

share of the P&L figures in these recaps are mangled in the underlying audio — the same trade quoted in rupees and dollars in one breath. This chapter uses only the cleanly stated numbers and flags the rest; a reader wanting a specific figure should watch the timestamped source.

Chapter summary

- The most complete walkthrough — Apollo Hospitals, no event behind it, sideways at the

level, short the candle, stop above the pivot for ~Rs 23 risk, target 40-43, outcome ~1:2 — contains every rule from Chapters 6, 8, 9 and 11 with nothing added.

- His gold trades run the same argument in two vocabularies: downtrend break, double

bottom, neckline break, retest for the long; fair value gap with the stop above the zone for the short, credited for the 1:4.

- A session can turn on instrument selection before any setup appears — Kotak dropped for

lack of momentum, SBI shorted over a choppy index.

- He offers one recap explicitly for management, not entry: \$3,500 up, \$1,000 negative,

booked \$6,000 — and shows the opposite outcome too, cutting early for half of a twelve-to-fifteen-lakh move.

- A correctly executed multi-timeframe setup can pay nothing — reported as a no-profit

no-loss trade.

- Across a three-day drawdown he doesn't change size — Monday and Tuesday losses,

Wednesday's normal-sized recovery trade; the same constancy appears as three attempts at the same \$4,000 risk.

- He narrates his own deviations rather than hiding them: entries before the candle

closed, entries on a lower timeframe than taught, size increased mid-trade on judgement.

Try this

He demonstrates a visual backtest on camera rather than describing one: taking a single pair, EURUSD, across a short defined window and counting outcomes — 8 targets against 3 stop losses. Do that, exactly as scoped: one instrument, one setup, one window of a few days, walked bar by bar, with each outcome written down as target or stop before you move to the next.

Then do the second thing he demonstrates on his own trades: record the non-numeric column alongside the result. Reading his own journal, the best day in it carries the habits next to the figure — stayed calm, wasn't dying to exit, self-esteem was high, didn't overtrade at all. For each trade

in your count, add one line on what you did while it was open, and compare that column against the outcome column rather than the total.

Appendix A — Books He Teaches From

In this appendix: the third-party material he walks through on camera — Steve Burns' *Trading Habits* and *New Trader Rich Trader*, the Jesse Livermore and Nicolas Darvas case studies, Dow theory, the Rakesh Jhunjhunwala case study, Napoleon Hill's *Think and Grow Rich*, Morgan Housel's *The Psychology of Money*, *The Richest Man in Babylon*, and the shorter reading list — what he covers from each and where his own commentary parts company with the source.

Every other chapter of this book excludes material that originates with someone else — a book about his method should report his method. This appendix is where that rule is lifted. Citations here point at *his* video, at the timestamp where he makes a point on the book's behalf — evidence of his walkthrough, not of the original text. His commentary and the source material are kept apart wherever he disputes a book, substitutes an Indian example, or rejects a rule outright; those interventions are flagged as his.

A.1 Steve Burns, *Trading Habits* — the psychology series

The single largest body of third-party teaching on the channel is his numbered walkthrough of Steve Burns' *Trading Habits*, a multi-episode 2021-2022 series.

Habit formation. Correct trading behaviour starts as rules followed deliberately and evolves into habit, until execution becomes subconscious. The chapter's three substitutions: replace opinions with trade signals, replace ego with position sizing, replace emotions with a trading plan. His own contribution is the worked translation: "buy the dip" is not a trading signal — the quantified version is waiting for a pullback into the 50-day moving average and buying when it turns up. Of the book's three qualities, "high probability setup" is the phrase he singles out as his favourite, and he says he trades only those, sitting out rather than forcing a low-probability trade with his own money.

Trends and best trades. A market in a strong uptrend doesn't suddenly turn down — a reversal builds slowly; a fast dip inside an uptrend finds a buyer and reverses. He cannot overstate how important the 200-day moving average is on these timeframes. His favourite point in the whole book: the best trades work right away and don't make you wait — price moves away from the stop shortly after entry, which is how you know it's working. The moment a trade proves itself, focus shifts from managing the loss to managing the winner.

Risk and sizing. A trade must end in one of four ways — small loss, small profit, big profit or breakeven — with the big loss removed from the portfolio entirely. The formulation he says he enjoyed most: the stop loss as insurance, a premium paid regularly that feels wasted until the one time it's needed. He walks a drawdown example — a one-crore account losing 10% five times through overtrading, needing a large gain just to recover — to make the asymmetry concrete.

Editor's note — the arithmetic in his drawdown example His figures are approximate. Five successive 10% losses compound to roughly a 41% drawdown, not 50% — one crore becomes about 59 lakh, needing roughly a 69% gain to recover, not 100%. The rounding doesn't damage the point: recovery always requires a larger percentage than the loss, and the gap widens fast — a 50% loss needs 100% back, a 90% loss needs 900%. The most-cited real illustration is the Nasdaq Composite after March 2000: down roughly 78% at the 2002 trough, it didn't regain its 2000 high until 2015.

Point 32 is where he breaks with the book: the rule as written is never to lose more than 1% of trading capital on one trade. He disagrees plainly — the cap is scaled to million-dollar accounts and too small for ordinary Indian retail capital. This is the clearest single example in the corpus of him refusing a rule from a book he otherwise teaches from.

A.2 Steve Burns, *New Trader Rich Trader*

The second Burns book gets a single-video summary, built on paired contrasts he relays chapter by chapter: new traders trade out of greed and fear, experienced traders trade a plan — which he calls the most important difference of the set; new traders fail where they stop learning, experienced traders never stop; new traders act like gamblers, experienced traders treat trading as a business; new traders try to prove they were right, experienced traders accept when they're wrong. He skips chapter 7 without comment.

A.3 Jesse Livermore

The Livermore video is the longest single piece of third-party teaching on the channel, a numbered lesson sequence through the biography.

Lesson one: the people losing money had no plan, no rules, no preparation — effectively gambling rather than trading. Gambling is predicting what the market will do next; trading is letting the market move first and entering according to whatever it does. **Probing and pyramiding:** entering with only a small part of capital on a breakout, exiting immediately if it doesn't work, and adding quantity each time it continues to work. His verdict is the important part: it's not a highly profitable

technique but a risk-control one, and he names it the part of Livermore's method he personally likes.

The failures: big money is made in the big swings, not daily trading for small gains. On the cotton trade where Livermore added money to a loser to save it: losing positions must not be averaged. The lesson from the loss that wiped him out: never become arrogant because of past success, never break your own rules.

The strategies: a big move on big volume means going straight for the breakout; big volume with no price movement makes the setup suspect. You don't need to know why price moved, only what happened — pushed to the stronger claim that you should never trade the news and follow only technicals.

His own summary of the whole method: find the trend and don't fight it; do what the market says, not what you think; cut losses small; let profits ride until the market gives a reason to exit; never trade cheap stocks; avoid tips and research yourself; and — the boundary he draws carefully — you will never become a trader while your trading *decisions* depend on someone else, though learning concepts from books is fine.

Editor's note — what the Livermore record does and does not

support Most popular Livermore material descends from Edwin Lefèvre's 1923 novelised *Reminiscences of a Stock Operator* and from *How to Trade in Stocks* (1940). Dialogue, exact figures and the tidiness of individual episodes in that literature are not documentary. The behaviours he draws out — scaling in on confirmation, cutting a probe fast, waiting in cash — stand or fall on their own logic rather than on whether a particular anecdote happened as told. He also doesn't mention how the story ends: Livermore was bankrupt more than once and died by suicide in 1940. A method taught from a life should be weighed against the whole of it.

A.4 Nicolas Darvas

Told as a sequence of failed shortcuts followed by a system: tips from professional contacts, paid newsletters, a broker's suggestions (who earns brokerage regardless of outcome), a mortgaged house funding a fundamental-analysis pick — all losses. What worked was careful study of price action and volume combined. That's where the Box Theory came from — he calls it literally the *dabba*, or box, theory: the market moves in a sort of consolidation range, somewhat wider than typical consolidation. Darvas worked on a weekly-closing basis and never went short, long only.

The behavioural half: once successful, Darvas moved next to Wall Street and the constant information flow led to overtrading; the fix was moving

the office far away and deliberately sleeping so as not to take impulsive decisions — the "sleeping trader" name. Darvas's closing points: he'll be wrong half the time, however good he gets; no emotional connection with any stock; there are no good or bad stocks, only stocks rising and falling in price.

Editor's note — the box, drawn He describes the box verbally and never draws its rules on a chart. In Darvas's own account — *How I Made \$2,000,000 in the Stock Market* (1960) — a box is a ceiling and floor established after a new high: the high it fails to exceed becomes the top, the low it holds on pullbacks becomes the bottom, and the position enters on a close above the ceiling with the stop just under it, re-drawn higher as the stock advances. Darvas ran the system by cable while touring as a dancer, receiving only weekly quotes — the practical reason for the weekly-closing basis, and why the method is structurally incapable of intraday use. He doesn't make that connection on camera.

A.5 Charles Dow and Dow theory

Taught as history first, then six numbered points, sourced to William Hamilton's 1922 book *The Stock Market Barometer* — published after Dow's death, so the six-point formulation is Hamilton's rather than Dow's own writing.

1. The market discounts all the news — narrowed during the explanation to "all the *obvious* information available at that point of time". 2. Three trends by direction, three phases by duration. 3. Every trend has three phases: accumulation, public participation, panic. 4. Indices must confirm each other — he transposes this to Nifty and Bank Nifty needing to confirm each other. 5. Volume must confirm the trend. 6. A trend persists until a clear reversal — he says outright this point is of no use to intraday traders.

A.6 The Rakesh Jhunjhunwala case study

Not a book, but the same format applied to a career. The biography is told through positions: Tata Tea bought at Rs 43, sold around Rs 143 for roughly 5 lakh; Titan, bought around Rs 3 after its IPO, grown into a multi-thousand-crore holding, credited to the power of investing and holding for a very long time.

Two rules relayed mid-video: learn from your own mistakes, don't repeat them; always observe the market closely and take independent decisions, never trade or invest on someone else's.

The closing seven points, scoped mostly to investors: stay optimistic and hold long-term hope regardless of the current market; trade or invest only within your risk appetite, never on loan or emergency money; never connect with a stock emotionally, since attachment breaks your stop-loss

discipline; the market always has momentum, know which trend it's in; holding is a decision, same as buying and selling; invest only comfortable money; accept when you're wrong and don't fight the market. He relays the stronger claim that the market is never neutral or sideways explicitly marked "according to him," not endorsed — it sits awkwardly against his own narration elsewhere of long sideways stretches.

A.7 Napoleon Hill, *Think and Grow Rich*

Taught twice — a book-summary video and a live meetup — as general life and success advice rather than trading rules. The steps: **desire**, a burning desire as the first test of whether you'll succeed; **faith**, in yourself and in god; **specialised knowledge**, translated for a trader into technical analysis, risk management and trading psychology; **visualisation**, seeing concretely where you'll be in one to five years; **decision**, taken firmly and once; **persistence**, introduced by his own admission of having failed many times; **the mastermind group**; and **the sixth sense** — trust your intuition, presented as a life-decision principle, not a trade-entry rule, which matters because everywhere in the method proper he requires a quantified technical signal before entry.

A.8 Morgan Housel, *The Psychology of Money*

Worked chapter idea by chapter idea. **Nobody is crazy** — people make financial decisions from their own experience, so calling gold or stocks or crypto unsafe can all be correct at once. **Freedom** — the point he says he likes most: freedom over your own time gives the highest return on investment. **Tails** — a small number of events account for the majority of results, roughly 10% of life's events giving 90% of the outcome. **Saving** as a pure habit, however small the amount. **Margin of safety** — keep one, don't put all your eggs in one basket. The closing line: financial success is a soft skill you develop slowly, not a hard science.

Editor's note — what "tails" means quantitatively He states the tail idea as a rough 10/90 split and moves on. The finding usually cited behind it is Hendrik Bessembinder's study of US common stocks from 1926 to 2016: the entire net dollar wealth creation of the market above Treasury bills came from about 4% of listed firms, and a bare majority of individual stocks underperformed one-month Treasury bills over their lifetimes. That's the strong form of the point — not that a few winners dominate, but that the median outcome is a loser and the average is carried entirely by the tail.

A.9 *The Richest Man in Babylon*

His most-repeated non-trading recommendation, always for the same purpose: saving as a habit prior to any question of returns. The person who saves without caring whether the amount is 10 rupees or 1 lakh is the one who builds a corpus; the person who postpones saving on the assumption future earnings will be higher ends up saving nothing. His restatement of the whole book: fix the habit and the money comes automatically. Three lines he quotes directly: a little caution is better than a huge regret; a rich man's job is to protect his gold — his capital — from losses; avoid any scheme promising very fast money or extraordinary returns.

A.10 The shorter reading list

Trading in the Zone — recommended as a mentor substitute during a fifteen-day break after a loss; his one-line summary: a person who can't accept that any given trade may lose can't be a trader, however good the setup. *Super Trader* and *High Probability Trading*, recommended in passing. *The Power of Your Subconscious Mind* by Joseph Murphy, which he calls the best book written on attracting wealth, relationships and peace. *Laws of the Spirit World*, which he names as a book that literally changed his life.

One body of published material he explicitly refuses to teach from is the candlestick literature — dismissed on camera as contradictory (one book

says 35 patterns, another 100), preferring to take students to the charts for the truth.

What he doesn't say about this

- **He doesn't give editions, translators or page numbers**, and the transcript loses

the title itself in places — *The Richest Man in Babylon* is rendered by automatic captions as "Richest Man of Baby Loan".

- **He doesn't finish what he starts.** The *Trading Habits* series covers points 1-15

and 28-32 across episodes with gaps; *New Trader Rich Trader* skips chapter 7 without comment.

- **He doesn't reconcile the books with each other or with his own method.** Burns' 1%

risk cap he rejects outright; Jhunjhunwala's "market is never sideways" he relays without endorsing; Dow's sixth point he calls useless for intraday traders. Beyond those flags, conflicts are left standing.

- **He doesn't assess sources.** Biographical stories are retold from memory with

uncaveated figures, and unverifiable anecdotes are presented as fact.

Appendix summary

- The largest third-party block is his numbered walkthrough of *Trading Habits* — habit

formation, trend behaviour, and risk sizing across three episodes.

- His clearest break with a source: rejecting Burns' 1%-per-trade cap as scaled to

million-dollar accounts, too small for Indian retail capital.

- The Livermore case study's part he claims for himself is probing and pyramiding — a

risk-control technique, not a profitable one.

- Darvas supplies the box method, weekly-closing, long-only, plus the lesson of moving

the office away from the information flow.

- Dow theory is taught as six points sourced to Hamilton's 1922 book, the sixth flagged

useless for intraday.

- Jhunjhunwala closes on seven points scoped mostly to investors, with the "market is

never sideways" claim marked as his rather than endorsed.

- *Think and Grow Rich* is taught as eight steps of life advice, specialised knowledge

translated into a trader's syllabus.

- *The Psychology of Money's* point he likes most: freedom over your time is the

highest return on investment.

- *The Richest Man in Babylon* is his most-repeated recommendation: saving is a habit,

prior to any question of returns.

- The one literature he refuses to teach from is candlestick-pattern books, dismissed as

self-contradictory.

Appendix B — Where the Method Is Silent

In this appendix: every gap the nineteen chapters found, gathered in one place and sorted by kind rather than by chapter. Nothing here is a new claim — each item is carried over from a chapter's "What he doesn't say about this" section, with the same card citations, so a reader can return to the chapter for context and to the card for the source video.

Read one chapter at a time, these endings look like ordinary loose ends. Read together, they fall into a small number of recurring shapes: figures stated but never sourced, rules that appear in several incompatible versions across five years of video, questions he argues both ways and leaves open, places where his own trading differs from what he tells viewers to do, and subjects the channel simply never covers. This is coverage-mapping, not criticism — a YouTube channel was never built as a textbook.

B.1 Unverified claims and self-reported statistics

The largest category. Almost every number in the method is his own estimate, usually hedged in the moment, unaccompanied by a trade log, sample size or date range.

His own record. He never gives a full, dated account of his trading — the figures are episodic, with no continuous series and no independent audit ([Ch. 1]). Chapter 19 finds the same gap from the worked examples: no period's complete trade set is ever shown, and he rarely states the account size behind a profit figure.

Setup hit rates. Every figure in Chapters 4, 5 and 7 is a labelled estimate — six or seven out of ten on fair value gaps, above 60% on the trap system, 65% of breakouts failing. On patterns the numbers are looser still, and a "9 out of 10" grade on candle setups is a subjective quality score, not a win rate. He consistently tells viewers to compute and verify these themselves — the right instruction, and the reason this book cannot report a tested edge for any setup.

Levels, stops, management, sizing. No hit rate exists for any level type or touch count (Ch. 6); stop-out figures are casual, with no comparison of candle-based against level-based stops on the same sample (Ch. 9); he never reads out his own sheet's exit-type percentages (Ch. 10). The win rates carrying the risk model — 60:40, seven-in-ten on option selling — are his own claims with no backtest output shown (Ch. 11).

The failure-rate statistic. Every figure in the corpus — 90 to 99 percent — is asserted or attributed to "the data" without citation, and his own subscriber poll produces a wildly different answer he never reconciles (Ch. 2, 16).

His students. He never gives a figure for how many of the five to eight hundred he says he taught became profitable, beyond an unsourced "five in ten pass if prepared" framing (Ch. 1). Psychology results, compliance percentages and recovery timelines are likewise self-reported and frequently self-hedged (Ch. 15).

Curriculum exclusions. The dismissals of harmonics and most named candle patterns are asserted as judgements without the backtest evidence he demands of others (Ch. 16). The same applies to instrument-specific exceptions in Chapter 13, each asserted from experience with no sample or count.

B.2 Costs, spread and slippage, absent from the arithmetic

This gap appears in almost every mechanical chapter and changes the meaning of every ratio quoted in the book. No brokerage, slippage, spread or tax figure appears in any setup specification — every win rate and ratio in Chapter 5 is gross. Entry mechanics address costs only in narrow exceptions (Ch. 8); the ratio floors in Chapter 9 are quoted gross and never restated net of costs; the sizing formula in Chapter 11 is always risk

divided by stop distance with no allowance for commission or slippage. For beginners, brokerage appears only in passing — the reason a Rs 20,000 planned profit fills at about Rs 19,500 — with nothing on how costs interact with a small account or high trade count (Ch. 16). The single place he nets costs out explicitly is one earnings-strategy recap, roughly Rs 14,000 net of Rs 4,000 brokerage on Rs 6.5-7 lakh deployed (Ch. 19).

B.3 Rules he states in incompatible versions and never reconciles

Cases where a number or definition exists in several forms across videos, with no statement that one supersedes another.

- **Risk per trade** spans 0.5 to 5 percent, with 7.5-8 percent named once — mostly explicable by account size and instrument, but never

stated as a revision (Ch. 11).

- **Risk-reward on funded accounts:** 1:1, 1:1.5, and 1:2 all appear, including in two

videos demonstrating the same trade both ways (Ch. 12).

- **Starting capital** ranges from \$250 to Rs 25,000, tracking instrument and year with no generating rule (Ch. 16).
- **Touch count for a level:** two, three-minimum-four-better, and three-to-six all

appear with no statement of which applies where (Ch. 3). **Structure counts** shift from three movements (2020) to two states (2024) to three shapes (2025), never treated as revisions of each other (Ch. 3).

- **Body or wick:** he instructs body in most videos and wick in some, sometimes

changing convention inside a single video (Ch. 6); the same ambiguity applies to fair value gap stop placement — beyond the gap, or at its 50% — given interchangeably (Ch. 4).

- **"Engulfing"** means the previous one candle in some videos, the previous three or

several in others — Chapter 7 flags this as the single most likely place a reader implements something other than what he trades.

- **The leverage ceiling** moved from 500x (Jan 2021) to 1:200 (June 2025), the

direction consistent with his broader stance but the revision never acknowledged (Ch. 17).

- **His own experience:** four years in 2021, six in 2024, fifteen in another 2024 video

— the discrepancy unaddressed (Ch. 1).

- **What counts as a good return** varies by instrument with no reconciling benchmark,

and the *period* for a return figure — "10%," "5-15%" — is usually unstated and shouldn't be read as monthly unless he says so (Ch. 16, 19).

B.4 Questions he argues both ways and leaves open

Distinct from B.3: opposed positions, both stated with conviction, neither withdrawn.

- **Psychology first or strategy first.** The 2025 "psychology only matters once you

have a tested strategy" directly reverses the 2022 "belief work comes before strategy work," argued both ways within a fortnight in mid-2025 (Ch. 2, 15).

- **Whether support and resistance still work.** A 2025 video agrees they don't work

today and that trap/liquidity trading has replaced them — against advice earlier in the *same video* about mastering zones and levels (Ch. 2, 4, 6).

- **Whether breakout trading is worth doing.** "Should not be done at all" (Nov 2025)

and "the era of buying the break is over" (June 2026) sit against breakout entries he continues teaching through the same period (Ch. 5).

- **Whether smart-money concepts are special.** He calls SMC an indicator anyone can

run, dismisses smart/dumb-money talk outright once, and elsewhere says what works turns out to be basic with no ICT concepts — while building most 2025-26 walkthroughs on exactly that vocabulary (Ch. 4).

- **Whether reversal patterns work outside equities.** 2026: useless in forex and

crypto. 2024: the double top works in both, and his own record includes forex, gold and crypto pattern trades that contradict the newer claim (Ch. 7).

- **System stop versus cutting by hand.** The instruction to viewers is always the

system; his own stated practice in options and several 2025-26 sessions is to cut by hand — a split he acknowledges without resolving (Ch. 9).

- **The June 2026 breakeven revision.** He says rushing to cost-to-cost ruined many

trades, and continues to use and teach the breakeven shift in the same period (Ch. 10).

- **Two entry-rule tensions:** buying only on a close above a level, then entering early

on a large green body; using the fair value gap as a trigger two weeks after telling students to stop using it as one (Ch. 4, 8).

- **Paper trading.** Beginners should do it; psychology won't come from it; a specific

student was told not to do it at all — no rule reconciles the three (Ch. 14, 15).

- **Break or trade through a losing streak.** A ten-to-fifteen-day break is prescribed,

and separately, never stop during a losing run — the backtesting precondition on the second is the only bridge, and he never states it as one (Ch. 15).

- **Event posture.** Stand aside, manage what you hold, and trade the event breakout all

appear as taught positions with no stated priority when they conflict, and his own most recent entries are of the third kind while his teaching is mostly the first two (Ch. 18).

- **Macro.** Daily global checklist to "macroeconomics is not what a trader needs" to

"never trade on correlation," with investing carved out as the only stated exception (Ch. 18).

- **Whether the broker matters.** Called the most important part of forex trading, and

elsewhere said not to matter as much as psychology — Chapter 17's reading is that the claims are scoped to different markets, but he never draws that boundary himself.

- **The funded-account reversal.** He changed course on funded accounts, citing

subscribers' emotions, without revisiting his earlier claim that any fee-based model "is not right" — which the products he later walks through all are (Ch. 12).

- **Profit videos.** He stopped making large-profit videos as harmful, while continuing

to show live profit as credibility evidence, with no stated line between the two (Ch. 1).

B.5 Where his own practice diverges from his stated teaching

- **"Never be stingy" with the stop** — given as an instruction, then shrunk on a live

trade minutes later, and taken deliberately tight when placing heavy quantity. The honest reading is that the rule is a corrective against a common beginner error rather than a description of his own trading (Ch. 9).

- **Always use a stop** — he ran a capital-heavy positional Bitcoin position with no

stop through late 2025, planning to hold through a 30% crash, while in the same period stating he'll never again trade without one (Ch. 11).

- **One considered entry versus step entries** — states he places one carefully-

considered entry, against a long record of step entries (Ch. 8).

- **Set-and-forget versus the discretionary layer** — demonstrates dozens of non-rule

exits while telling beginners to set and forget, with no stated crossover point (Ch. 10).

- **The pyramiding cap** he names is broken in the same video that states it (Ch. 10).
- **Journaling** — he wrote very little himself in the eighteen months before the 2025

format video, because his own trading is automated and team-run, while insisting the journal remains essential for manual discretionary trading (Ch. 14).

- **The routine** is described from a full-time trader's position, and he reports

managing only 60-75% of it himself (Ch. 14).

- **Choosing markets** — he documents his crypto retreat and shift toward futures and

gold without stating the decision rule behind it; his own advice ("let your statistics tell you which asset you're profitable in") isn't the process he narrates for himself (Ch. 13).

B.6 Judgement calls he leaves undefined

Places where the method relies on a discretionary reading he declines to operationalise — a fair position for a discretionary trader, but a reader building a rulebook has to fill each one in personally.

- **Zone width** — switch from line to rectangle "when turning points cluster

messily," never a width in points, ticks or ATR multiples (Ch. 3).

- **"Important level"** beyond the three-or-four-touch criterion is left to the reader

(Ch. 5). **"Big candle"** gets a floor in some strategies and stays a visual judgement ("clear," "solid," "power") elsewhere, with no numeric threshold overriding his two-candle rule (Ch. 8).

- **Terms named but not defined** — a pivot's formula he explicitly refuses to teach; a

chart's "base" with no formal criteria; a "type two" structure never distinguished from type one (Ch. 3).

- **The stop buffer** ("a little beyond the level") and **which stop reference to use**

(candle low, swing low, moving average, pivot, zone edge) are both given per-trade, never generalised into a formula — his 2020 "whichever is nearest" is contradicted by his frequent preference for the wider option (Ch. 9).

- **Which liquidity level wins, which timeframe wins, and which setup wins**

when two qualify at once are each answered only by worked examples, never a priority rule (Ch. 4, 5, 6).

- **Which market state you're in** — the three-state framework is the model's base, but

beyond an ADX threshold and a later ATR-consumption check, there's no stated procedure for deciding when a trend becomes a range. He says explicitly that nobody can tell you where a trend ends (Ch. 2). The crypto bull/bear phase filter, his strongest crypto instruction, is never operationalised beyond a single level treated as a call rather than a method (Ch. 13).

- **When a pattern has stopped working** — no pattern works permanently, he says, but no

test for recognising the change or rule for retiring one (Ch. 7).

- **Whether a run-up is already priced in** — the whole anticipation framework depends

on this with no stated threshold (Ch. 18).

- **A legitimate rule change versus a rationalisation** — no test distinguishes them

beyond the general instruction to review weekly (Ch. 14).

- **Sample size per bucket**, and what to do with a backtest landing at exactly 51%

— the boundary case his own "above 50" rule leaves undecided (Ch. 14).

- **The emotional states** — "greed," "fear," "ego," "FOMO" are used throughout with no

test to distinguish a fear-driven exit from a legitimate discretionary one (Ch. 15).

- **When a beginner stops being a beginner** — nearly every instruction in Chapter 16 is

scoped to this boundary, and he never states a test for crossing it.

- **Deferred topics** — stop placement in options called "a little tricky" with the

method never given; no sizing calculation in the video where he says quantity must come from one; the timing theory behind his packaged trap system left unexplained because it "would make the video too long" (Ch. 4, 9, 16).

B.7 Topics the corpus does not cover at all

- **Market microstructure** — almost nothing on market makers, exchange auction

mechanics, or order-book depth; the "institutions are moving the level" claim is inference from his own order behaviour, not observed order flow (Ch. 2, 4). He never explains the discounting mechanism itself — how information gets into price before an announcement — nor addresses disclosure rules or insider-trading law (Ch. 18).

- **Volume** plays almost no role in level selection or pattern work outside the

volume-profile strategies; the classical requirement that a breakout be confirmed by expanding volume is absent from his rules entirely (Ch. 6, 7).

- **Measured-move targets** — the classical geometry (projecting a pattern's height from

the break) isn't part of his method; he never states or dismisses the convention (Ch. 7).

- **Portfolio-level risk** — no method for aggregating risk across simultaneous

positions; correlation is addressed only twice and anecdotally (Ch. 11).

- **Gap and liquidity risk** in the sizing formula — he shows the damage a gap can do

and treats the 24-hour forex session as the market where a stop is never skipped, but the implicit advice is to trade elsewhere rather than a stated method for sizing around gap risk when you can't (Ch. 9, 10, 11).

- **No volatility-scaled stop rule** — he rejects fixed-percentage and fixed-size stops

but offers no substitute measure; ATR appears only as a target check, never a stop input (Ch. 9).

- **The option seller's tail** — the seller's win rate is given loosely, but no losing

example is worked through the way the buyer's decay is (Ch. 13).

- **Macro forecasting** — CPI and rate decisions are explained as calendar entries only;

there's no forecasting content, and by his own account there shouldn't be (Ch. 18).

- **A test for a legitimate prop firm** — he's said outright he doesn't know which firms

are genuine; his later due-diligence criteria are all disclosure proxies, none of which test whether a firm will honour a large unexpected withdrawal (Ch. 12).

- **A test for an A-book broker** — every substitute criterion (size, age, footprint,

payout history) is a reputational proxy that doesn't read the actual order routing (Ch. 17).

- **What to do after you've been defrauded** — no complaint procedure, regulator, or

recovery step is given anywhere (Ch. 17).

- **Tax, everywhere** — nothing on funded-account income for an Indian resident, no

beginner-specific treatment, no tax line in the sizing formula (Ch. 11, 12, 16, 17).

- **Automation** — his own trading is now automated and team-run, but what the process

layer should look like for a partly-automated trader is not covered (Ch. 14).

- **The clinical end of what he raises** — he reports messages from viewers describing

suicidal ideation after large losses and describes traders in heavy depression; his prescriptions are a detox week, meditation and a break. He never suggests professional help or says this is outside what a trading channel can address (Ch. 15).

A note from the editors, not the creator: if trading losses have brought you to thoughts of self-harm or suicide, that is beyond what any trading method, journal, or meditation practice can address, and beyond the scope of this book. In India, the KIRAN mental health helpline (1800-599-0019, toll-free, 24/7) and iCall (9152987821) offer confidential support; readers outside India can find a local crisis line at findahelpline.com. Please reach out.

B.8 Legal, regulatory and tax statements made without qualification

Forex legality. He states flatly and repeatedly that forex from India is illegal, and in the same body of videos supplies a payment structure he argues makes it lawful in practice. Both positions are stated as certainties, never as being in tension, with no source cited for the P2P argument and no professional qualification offered (Ch. 13, 17).

Accounts in another person's name. He tells a viewer with a government job to trade through a sibling's or parent's account with no

legal, tax, KYC or employer-rule qualification — sitting oddly beside his own repeated rule never to share credentials (Ch. 1, 17).

Crypto legality and tax. He says crypto is entirely legal on inferential rather than statutory grounds, and his one tax claim (international profits attract no tax) contradicts his own "other income" guidance elsewhere — while he separately tells viewers to check the crypto tax position with their own accountant (Ch. 13).

His SEBI registration. He asserts it and mentions one restriction it imposes, but never states the category, its scope, or what it does not permit (Ch. 1).

B.9 Limits of the source record itself

Transcription noise — a substantial share of P&L figures in the recaps are mangled in the underlying audio; this book uses only cleanly stated numbers and flags the rest. **Hindi vocabulary** — some private

terminology is not recoverable from transcript alone. **No external terminological anchor** — no reference to Edwards and Magee, Wyckoff, or any exchange/regulator definition appears anywhere in the material.

****Clock time**** — session times are given in Indian clock time and rarely converted, and several individual references are internally inconsistent.

Which data feed — he warns level numbers change between brokers, and in 2026 says the biggest mistake he'd been making was studying a

fabricated retail gold price — without going back to revise the levels taught in earlier videos in light of it.

How to use this appendix

Three practical readings. First, where a number is unsourced, treat it as a hypothesis to test rather than a parameter to adopt — which is what he tells viewers to do themselves, repeatedly and without being asked.

Second, where a rule exists in several versions (B.3), date it — almost every spread resolves into a sequence once the video year is attached, even though he never announces the change. Third, where a question is genuinely open (B.4) or a judgement is undefined (B.6), the reader has to close it themselves and hold the choice constant — not a workaround for a defect in his teaching, but what discretionary trading is — and the choice should be written into the plan and reviewed like any other rule, the way [[Ch. 14]] describes.

Appendix C — Glossary

Every entry below is his own working definition, paraphrased from the videos and carrying the source marker of the card the chapters cite for it.

Where a term's meaning drifts across the years, the entry says so. Blocks marked **Editor's note** are compiler-added context and never his claims.

70-30 rule — His only quantified candle-quality criterion: the entry candle should be about 70% body in the direction of the trade, with the wick under 30%.

Area of interest (AOI) — His umbrella term for a marked region price is expected to react from — an area from which the market *may* turn, not will. He states as an absolute that you never trade without one.

At-the-money (ATM) — The strike nearest the current price of the underlying. When you switch from a call to a put, ITM and OTM swap but ATM stays the same strike, since ATM depends only on nearness to price.

Averaging — Adding quantity to a position that's in loss. The forbidden move: never increase quantity while red — a habit and a losing strategy, as opposed to pyramiding, which is to be done.

Base — The area a market builds and then turns from, used without formal criteria.

Bear trap / bull trap — A bear trap is price falling below a level and closing back above it with a solid green candle. A bull trap is the mirror — a breakout that invites the bulls in, followed by a red candle that traps them.

Body / wick — The thin wick runs high to low; the thicker body runs open to close. The wick shows where price does *not* want to go; the body

is control and power. He draws levels mostly from bodies but is inconsistent, finally settling on comparing like with like — wick against wick, body against body.

Box — The market taking support and resistance at the same places repeatedly, several times before it counts.

Break of structure (BOS) — In his translation, simply a breakout of some level — price breaking above the previous high to create a higher high after a higher low.

Breakout — A level giving way, counted only on a candle *close* beyond it, never a wick. His three qualities of a good breakout: the market consolidated a little first, the level had failed several times already, and the move began close to the level rather than far from it. He states most breakouts fail, once putting the figure at 65% — which is why he prefers the trap and the retest.

Change of character (CHOCH) — A trend change — price taking a rejection and making a new low after a break of structure.

Confluence — Two or more independent readings landing on the same price at the same time — the junction of two rivers, the same reading appearing on two timeframes. More confluences means greater trade quality, though he shows confluence trades that lost anyway.

Consolidation — The market going sideways, taking one step back before a big move. An old consolidation area becomes a support zone for later trading.

Delta — Not taught formally — defined informally as "money on movement," the power of the movement.

Demand zone / supply zone — The zone-shaped version of support and resistance, also called an order block. The zone below price is demand, above is supply — the supply zone is the area price is expected to start dropping from.

Directional option selling — Selling the option on the opposite side of the view rather than buying on the same side, with hedging. He teaches directional, not non-directional, selling — you earn if you're right or sideways, not if it goes against you.

Doji (confusion candle) — Net output zero: price going up and losing, going down and losing. Never a confirmation candle or an entry — only a hint a reversal may have come. One of his three candle types, alongside power and rejection.

Dollar index (DXY) — The dollar measured against other currencies, 100 the stable level, above stronger, below weaker. He's emphatic it's a view layer, not a trigger — deliberately left out of his course as only an extra confirmation.

Double top / double bottom — Price rejected from the same resistance a second time, forming an M; the double bottom is the mirror, a W. Notably, the *breakout direction decides the name* — the same two touches become a top if the break is down and a bottom if up. He never enters at the second top or bottom; see **Neckline**.

ECN / STP broker — His two-way split of forex brokers. An STP broker passes your order straight through to the liquidity provider, earning from the spread regardless of whether you win or lose; a non-STP broker takes the other side of your order itself. He dismisses "ECN" as meaningless, saying it just means dealing over the internet.

Engulfing — See **Power candle**. His own definition is unresolved: in 2022 a candle counts as engulfing once it breaks the high of the single previous red candle, while elsewhere he uses it for a candle swallowing the previous three or several.

External liquidity / internal liquidity — External sits outside the structure at the extreme highs and lows; internal sits inside the range. External trades he calls more sure-shot; internal-liquidity trades are also good provided the level has had two or three touches.

Extrinsic value (time value) — The part of an option's premium determined only by time. Out-of-the-money options carry only time value. He flags his own simplification — practically, extrinsic value can be taken as theta, though a technically correct speaker would separate them since rho, vega and gamma also affect price.

Fair value gap (FVG) — The space left between the first and third candles of a three-candle sequence built around a very large middle candle — an imbalance between buyers and sellers. He holds that wherever there's a gap there's also an order block. His measurement is inconsistent — wick-to-wick or body in one video, body specifically in another — and he never states which to prefer. Filled gaps get deleted; only unfilled ones are extended forward.

Flag and pole — "Flag" simply means consolidation. A bullish flag is a strong breakout upward followed by a consolidation drifting back down at an angle, drawn as a parallel channel, bear flag its mirror.

Four quadrants — His framework for what a trader must have: technicals, risk management, psychology and life management, all four required before a trader can earn.

Gamma blast — A fast candle in your favour that increases delta so the P&L expands out of proportion to the move.

"Good stop loss" — A loss that had to happen according to your strategy, treated as learning rather than error.

Head and shoulders — An extended double top, sold when the neckline under the shoulders and head breaks. In plain terms: the market can't break the level, then breaks it but can't hold it, then can't break it again. Real ones are lopsided; the only constant is the right shoulder stays below the head.

Hedge — Two senses. Real hedging is protecting an existing long cash or futures position by buying a put or shorting a call. Generally, a second leg alongside your trade that saves you if something goes wrong, never for profit, always to cover loss. Its second job is margin relief.

HTF / LTF — Higher time frame, used only for analysis; lower time frame, used to take action. The action timeframe is always one step below the analysis timeframe.

Impulsive wave — A trending move, opposed to the corrective wave that follows. The invalidation rule: the corrective wave must always be smaller than the impulsive one.

In the money (ITM) / out of the money (OTM) — His test: read the contract name aloud as a present-tense sentence — true now, ITM; false, OTM. He advises beginners to buy ITM, then corrects it: the real requirement is not that you buy ITM but that when you *exit* you are ITM.

Intrinsic value — The part of the premium that comes from the chart, existing only in in-the-money options. He warns against abbreviating it "IV," since IV on the option chain means implied volatility.

Invalidation — The pre-marked technical level whose breach means the idea is dead. You know you were wrong when the market gives a *closing* beyond that level — not a retest, not a wick.

Editor's note — invalidation is not the stop-loss order. He runs the distinction constantly without naming it. Invalidation answers "is the idea still true?"; the stop-loss order answers "how much am I willing to pay to find out?" They can sit on different charts and different prices, and both have to be written down before entry, or the tighter of the two gets discovered emotionally.

IV crush — The collapse of volatility after an event — vega in the Greeks, implied volatility on the chain, India VIX in simple words. His rule: whenever India VIX falls, option premium falls.

Level — The primitive of his whole method. Support is a price the market repeatedly stops falling at; resistance is a level it's repeatedly unable to rise above. Neither is a property of the level itself — the name depends on where price currently sits. A level counts as *key* only with a minimum of three touches, four preferred, though two makes a line worth drawing.

Editor's note. His ceiling-fan image has a textbook name he never uses: **polarity**, or the support-resistance flip, described in Edwards and Magee long before charting software existed.

Leverage — Borrowing from the broker. His settled position: leverage is the wrong question — you should ask how much risk to take, starting from risk and letting everything else follow.

Liquidity — Technically, where the orders are — resting buy and sell orders. The version he actually trades is narrower: an area where other traders' stop-losses or targets are sitting. He corrects the common retail version: liquidity doesn't sit only at highs and lows.

Liquidity sweep (liquidity grab) — The market going into a trap area and coming back; what he calls a trap is what others call a liquidity sweep. See **Trap**.

Logical stop — A stop placed on a chart fact rather than a chosen distance. Two tests: it sits on a support or resistance level, and if the required stop would cost more than the allowed percentage of capital, the trade is disqualified rather than the stop shrunk. His 2020 list of reference

points: pivot, moving average, level, or the day's high/low — whichever is nearest.

Lot — In forex, one standard lot is a hundred thousand units of base currency, moving ten dollars per pip; 0.1 lot moves one dollar per pip. The lot size is always an output of the risk calculation, never an input.

N pattern — Price running up, sent back down, then sent up again — a reversal-type structure, later made a precondition for breakout trading, while conceding it works "50, 60, 70 percent of the time, sometimes only."

Neckline — Nothing more than a minor support — the small support between the two tops. The rule is absolute: never enter right at the top of a double top, wait for the neckline to break, since entering at the extreme is too weak a setup.

Editor's note — why this is the testable part of pattern trading. "A double bottom formed" is not a testable event, since the tolerances come from a human eye. "The market closed beyond a specified price" is. Moving the entry from the shape to the neckline converts a subjective pattern into a conditional order with a defined trigger.

Order block — The small candle sitting immediately before a very large impulsive candle, marked high to low, extended forward as a zone — equated outright to the supply or demand zone. His main validation rule:

the wick must not have been completely inserted into the block, or the zone is violated.

Editor's note. "Order block" and "supply zone" are drawn by different rules even though both mark a place price is expected to react. The observable half of his rationale — a candle far larger than its neighbours means resting orders on one side of the book were consumed — is a real microstructure event; the second half, that the party responsible left unfilled orders behind and will return to defend them, is a model of intent with no order-book evidence supplied.

Pip — Operationally, the fourth digit after the decimal, 0.0001; yen pairs are the exception, using the second decimal.

Placement — Where price sits within the structure when a pattern forms. A bearish pattern is taken at a structure top, bullish at the bottom; placement matters more than shape, size or colour.

Position sizing formula — Quantity equals risk per trade divided by the size of the stop loss, both in money. The chart supplies the stop, the quantity adapts, never the reverse.

Editor's note. This has a name in the literature — fixed-fractional position sizing — the sizing convention used by essentially every managed futures programme since the original Turtle rules. Its known cost, which he doesn't address: position size becomes very large when the stop is very tight.

Power candle — His rename for the fat-bodied candle with small wicks; he says outright he substitutes his own vocabulary for the textbook "engulfing" to make it easier for beginners. One of his three candle types.

Premium / discount — Built on the fair value gap's 50% midline: entries from the lower half of a buy-side gap are quality entries, upper half low quality — the stated reason is stop-loss size.

Price action — Whatever action price itself takes, read off a plain chart.

Probing — Entering with a small position, adding only if it goes your way, otherwise leaving it and accepting the loss. He credits the technique to Jesse Livermore and adapts it as a 50/50 split rather than Livermore's positional version.

Pullback (correction, corrective wave) — All three are one term: a move against the main trend. The market never rises in a single go — it makes a high, pulls back to a shallower low, then makes another high.

Pyramiding — Adding to a trade that's already winning, so it pays two or three times more without raising risk by the same amount. The mechanism

that keeps it risk-neutral is the stop, not the entry — shifting the stop when quantity doubles is mandatory.

Rejection candle — His rename for the hammer and its inverted mirror: a tail below and a body above at a low. Its other name, he says, is the pin bar.

Retest ("retest theory") — Once a resistance is broken and price comes back to it, the old resistance now acts as support. His default entry — always trying to trade the retest rather than the breakout itself — though in a trap he says the opposite, that waiting for a retest is a mistake there.

Risk of ruin — Used loosely, as the risk of financial ruin.

Risk per day (RPD) — A fixed daily loss amount you stop at once hit, derived from the per-trade figure and trade count, with 5% of capital as the ceiling. The count version — the most important rule, he calls it — is two stop losses and the day is over.

Risk per trade — The fixed fraction of the account you decide in advance not to lose on one trade. Stated figures range from 0.5% for beginners through 1-2% standard to 3-5% for very small retail accounts, on a sliding scale by account size. The percentage applies to the size of the loss, not to capital deployed.

Risk-reward ratio — Defined by worked example: risking \$5 to make \$10 is 1:2. His floor is 1:1.5, working default 1:2 — never below 1.5, because the habit and quality get spoiled. The ratio is an output of the levels, not an input.

Editor's note — the ratio and the hit rate are one number. A

strategy breaks even when the win rate equals $1 \div (1 + R)$. At his 1:1.5 floor that's 40%; at 1:2, 33.3%; at 1:3, 25%; at the 1:1 he prescribes on funded capital, 50% — before costs.

Sniper entry — His named confluence template, the trap and order block welded together: finding a liquidity level, letting it break, getting a support after the break, entering on the reversal from there.

Spread — The gap between buy and sell price. He uses it as a live filter: in a good pair the spread shouldn't exceed one or two pips.

Stop loss — Defined twice. Mechanically, an instruction to the broker to cut the trade at a set price. Substantively, and this is the definition that carries his method: the point at which, if price reaches it, he is wrong. Two operating rules: never be stingy — place it a little beyond the level, never flush against it — and touch basis for beginners, closing basis reserved for the experienced. The stop belongs in the system, not in your head.

Editor's note — a closing-basis stop cannot be a resting order.

Exchange and broker stop orders trigger on traded price, not bar close, so a close-based rule is necessarily discretionary — someone has to watch for the close and send the order. That's why the loss between trigger and close is unbounded.

Straddle — Buying both the call and the put at the same at-the-money strike; short version is selling both. High-risk high-reward against the strangle's low-risk low-reward; his single biggest warning is not to break the straddle by closing the profitable leg alone.

Strangle — Shorting a call above the range and a put below it, so both decay to zero if price stays inside. The most famous structure among sellers, he says.

Super setup — His threshold for buying options rather than selling them: double or triple confirmation, or a strong trap. You buy only when you have one, which is rare.

Swing — One low joined to one high, also called a range. Highs and lows are counted by candle colour, not by eye.

Target — Chosen from the chart before the ratio is checked: stop goes on first, logically, then the target at the next resistance identified on the chart rather than derived from a ratio, then a check on the resulting ratio. His asymmetry rule: miserly with the target but never with the stop, booking just short of the crowded level because everyone can see it.

Technical analysis — Defined operationally: finding where to buy, where to sell, where to book the target, and where to cut the loss when it goes against you — no knowledge of the company's revenue or balance sheet.

Theta / self-destructing asset — An option is self-destructing because its theta runs negative — a hundred-rupee option can close at ninety even if

the underlying ends exactly where it opened. His teaching image is ice: taken out of the refrigerator it only melts, never doubles.

Trap — His core setup and the term he returns to most. The market opens, breaks a prior level and fails there — he explicitly equates it with a liquidity sweep. Structurally: price breaks a level, comes back inside it. The trigger is a *close* back inside, not a wick; the break should be small, not a massive run past the level; and in one formulation it should be quick — within roughly forty to fifty minutes. A **trap trader** enters where the maximum number of people's stop-losses are hitting.

Editor's note — "**false breakout**" is the standard name. The mainstream term for what he describes is a false or failed breakout — Toby Crabel's opening-range work and the "turtle soup" pattern published by Raschke and Connors in 1995 are both built on this shape. His 65% failure figure is his own and not sourced to any study.

Trend — An uptrend is higher highs and higher lows; a downtrend is lower highs and lower lows. He adds a clarity test: you can't call it a trend until the pattern has clearly formed. He suspends the trend rule for intraday traders, telling them to be totally neutral biased.

Trend line — A line drawn at an angle touching successive swing points of a trending move. He is deflationary about it: a trendline by itself does nothing — you can draw a hundred of them, and what matters is the action you get at it.

Triangle — Ascending: roughly equal highs against resistance with each successive low higher. Descending: lower highs, support flat underneath. Symmetrical: price consolidating between two trendlines. Entry rule is uniform: only on the breakout, never earlier inside the pattern.

V pattern — His self-declared favourite: a fast recovery, entered with full size once the V has formed and the breakout confirms — the breakout is the trigger, not the V itself.

Wedge — Almost the same as a flag, except the consolidation doesn't fit a parallel channel, drawn manually with two separate trendlines.

Zigzag theory — Price falling and rising in alternating legs. He adds an asymmetry: the market's nature is zigzag on the way up and like a bouncing tennis ball on the way down.

Zone — The thick area the market has hit repeatedly, versus a single support/ resistance line. By 2026 the preference has hardened into instruction — stop drawing lines, use boxes instead. He gives no rule for how wide a zone should be.

Appendix D — Source Index

Every source marker used in this book, grouped by video. Each video's title links to the video itself; the marker beside each is its timestamp there.

Appendix E — Method and Coverage

This book was assembled by a transcript-driven pipeline rather than written from memory or impression, which is what makes the source markers meaningful.

Coverage

Videos in the archive	2315
Videos read and processed	399 (17%)
Videos cited in this book	311
Total transcript words read	3,169,836
Publication range	2020-05-17 to 2026-08-17
Distinct claims extracted	14568
Claims cited in this book	1348
Words of finished text	68,892

How it was built. Each video's transcript was read individually and reduced to atomic, timestamped claims — one idea per record, with the conditions attached and a short locator phrase so the moment can be found again. Those records were then grouped by concept across the whole archive, which is how the chapter structure was determined: topics returned to across many videos became chapters, topics mentioned once became footnotes or were left out. Chapters were drafted only from the records belonging to that concept, then checked mechanically so that every claim-bearing sentence resolves to a real record, and checked again by sampling to confirm the records actually support the sentences citing them.

What this method cannot do. Transcripts capture speech, not screens. Anything shown visually and not described aloud — chart annotations, on-screen text, code — is absent from the source material and therefore

absent here. Automatic transcripts also mishear technical terms, so specific names and numbers were treated with suspicion and cross-checked across videos where possible. Where the creator was ambiguous, this book reports the ambiguity rather than resolving it.

On the two tiers. Material attributed to the creator is paraphrased from the transcripts and carries a source marker. Material in Editor's note boxes is added context from the compiler and is marked as such throughout. The separation is deliberate and strict: nothing in an Editor's note should be read as something the creator said.

Appendix F — What the Channel Does Not Cover
